I. ABSTRACT

On January 23rd and 24th, 1974, York Research, an independent consulting firm in the environmental field, began a series of emission sampling tests at the Willimantic Sewage Treatment Plant in Willimantic, Connecticut.

The purpose of these tests was to determine compliance with Connecticut State Regulations for particulate emissions from an incinerator. NO_x , SO_x , hydrocarbons and CO were also tested per a State request.

The Connecticut State Regulations as specified in "Administrative Regulations", Department of Environmental Protection, Abatement of Air Pollution, May 23, 1972, Page 14B, Section 19-508-18 "Control of Particulate Emissions" subsection (C) (3) (1) "Emission Standards. Particulates" states:

No person shall construct, install, use or cause to be used any new (constructed or modified after June 1, 1972) incinerator which will result in particulate matter in the effluent in excess of 0.08 gr/SCF (0.18 gm/NM³) corrected to 12% CO_2 , maximum 2 hour average. No person shall use or cause to be used any existing incinerator which will emit more than 0.4 lb. particulate/1000 lbs. of flue gases adjusted to 50% excess air.

The following Table gives the results of the scrubber outlet sampling in terms as used in the Connecticut State Regulations.

<u>Particulate Test</u>	<u>gr/SCF (12% CO_2)</u>	<u>lbs./1000 lbs. (Flue Gas @ 50% excess air)</u>
1	.137	.155
2	.208	.198
3	.264	.252
Average	.203	.202
State Limitations	.08 gr/SCF (12% CO_2)	.4 lbs/1000 lbs. (Flue Gas @ 50% Excess Air)

III. GENERAL TEST METHODS

DESCRIPTION OF OPERATIONS

The incinerator is a multiple-hearth furnace with six (6) hearths. The temperatures in the furnace are regulated by burners located on hearths 2, 4 and 6. The furnace is designed to burn 8000 lb./hr. of a mixture of primary and secondary sludge.

As the sludge is burned, a relatively large amount of gases are produced. What remains after combustion is a sterile ash which is transported to another location by some suitable means. Along with the combustion gases produced by the sludge and auxiliary fuel (if any) is particulate matter. This particulate matter is passed through a pre-cooling chamber and a scrubbing system which removes the dust particles.

The scrubber is an impingement type using 300 GPM total water for adequate scrubbing of gases. The scrubber has an outlet volume of 7160 ACFM (maximum) @ 120°F with a differential pressure of 6.5 W.C. at the designed scrubber outlet volume with a design outlet dust loading of approximately .03 gr./standard dry cubic foot exhaust gas.

The exhaust gases are moved through the entire system by an induced draft fan located between the scrubber outlet and the stack, and designed to move 8000 CFM at 120°F (See Figure #1).

SAMPLING LOCATIONS - PORTS

Particulate sampling ports at the outlet were located in accordance with EPA guidelines. The sampling ports were located so that the distance to nearest interferences upstream (6 duct diameters) and downstream (1.5 diameters) were far enough away as not to cause any undue turbulence in the gas flow (Figure #2).

FIGURE #2

SAMPLING LOCATION - TEST POINTS

The round 23 1/2" ID outlet stack had two ports at right angles (90°) for twenty test points (ten at each traverse).

The test points were sampled for five minutes each. The location of each test point was determined from EPA specifications (Figure #3).

FIGURE #3
OUTLET
SAMPLING POINT LOCATIONS

III. GENERAL TEST METHODS

Particulate Sampling Train - EPA Method 5

The sampling apparatus consisted of a five (5) foot probe, cyclone bypass, filter, four impingers, dry gas meter, vacuum pump and flow meter (See Figure 4). The stainless steel, button-hook type probe tip (1) was connected by a stainless steel coupling (2) with asbestos packing to the probe. The probe (3) consisted of 5/8 inch outside diameter medium wall Pyrex glass tube with a ground balljoint on one end. The probe was logarithmically wound from the entrance end with 26-gauge nickel-chromium wire. During sampling, the wire was connected to a variable transformer to maintain a gas temperature of 300°F in the probe. The wire wound tube was wrapped with fiberglass tape and encased in a 1-inch-OD stainless steel casing for protection. The end of the steel probe casing does not have the balljoint protruding but has a nut welded to it for connection to the stainless steel coupling used to attach the nozzle. The probe connects to a cyclone bypass (4). The cyclone bypass connects to a very coarse fritted glass filter holder (5), which holds a tared glass fiber filter. The cyclone, flask, and filter were contained in an electrically heated enclosed box (6) which is thermostatically maintained at a minimum temperature of 300°F to prevent water condensation. Attached to the heated box was an ice bath (7) containing four impingers connected in series with glass balljoints. The first impinger (8) receives the gas stream from the filter. This impinger is of the Greenburg-Smith design modified by replacing the tip with a 1/2 inch ID glass tube extending to 0.5 inches from the bottom of the flask. This impinger was initially filled with 100 milliliters of distilled water. The second impinger (9) is of the Greenburg-Smith design and like the first was initially filled with 100 milliliters of distilled water. The third impinger (10), which was left dry, is a Greenburg-Smith impinger modified like the first. The fourth impinger (11) is also a Greenburg-Smith type modified like the first and contained dry silica gel.

From the fourth impinger (11) the effluent stream flows through a check valve (13); flexible rubber vacuum tubing (14); vacuum gauge (15); a needle valve (16); a leakless vacuum pump (17), rated at 4 cubic feet per minute at 0 inches of mercury gauge pressure and 0 cubic feet per minute at 26 inches of mercury gauge pressure, and connected in parallel with a bypass valve (18); and a dry gas meter rated at .1 cubic foot per revolution (19). A calibrated orifice (20) completes the train and was used to measure instantaneous flow rates. The three thermometers (12) are dial type with a range of 25° to 125°F. A fourth thermometer in the heated portion of the box has a range up to 500°F. The dual manometer (21) across the calibrated orifice is an inclined-vertical type graduated in hundredths of an inch of water from 0 to 1.0 inch and in tenths from 1 to 10 inches.

PARTICULATE SAMPLING TRAIN

FIGURE #4

Readings Taken

During each run the following readings were taken at each point:

1. Point Designation
2. Clock Time
3. Dry gas meter reading (CF)
4. Velocity head (ΔP in inches water)
5. Desired pressure drop across orifice (ΔH in inches of water)
6. Actual pressure drop across orifice (ΔH in inches of water)
7. Dry gas temperature ($^{\circ}F$) gas meter inlet
8. Dry gas temperature ($^{\circ}F$) gas meter outlet
9. Vacuum pump gauge reading (in. Hg)
10. Filter box temperature ($^{\circ}F$)
11. Dry gas temperature ($^{\circ}F$) at the discharge of last impinger
12. Stack temperature ($^{\circ}F$)
13. Stack pressure (inches water)

The relationship of ΔP reading with the ΔH reading is a function of the following variables:

1. Orifice calibration factor
2. Gas meter temperature
3. % moisture in the flue gas
4. Ratio of flue gas pressure to barometric pressure
5. Stack temperature
6. Sampling nozzle diameter

A nomograph was used to correlate all the above variables such that a direct relationship between ΔP and ΔH could be determined by the sampler within fifteen seconds and isokinetic conditions maintained throughout the test.

ANALYTICAL PROCEDURE - PARTICULATES

The filter discs were previously tare-weighted and the weights recorded at York Research's Laboratory. Upon return they were dried, cooled in a dessicator, then weighed on an analytical balance. The amount of particulate collected is the difference in the weights. The probe and nozzle water and acetone wash solutions are placed into respective tared beakers, evaporated with an infra-red lamp and the beakers weighed again. The difference in the weights is the weight of the particulate in the washes. These are combined with the filter catch as the total weight of the sample.

PARTICULATE CALCULATIONS

The following are the basic equations used in calculating final data as found in the final summary.

1. Volume of dry gas sampled at standard conditions - 70°F, 29.92" Hg, ft.³

$$V_{mstd} = \frac{17.7 \times V_m \left(\frac{P_b + P_m}{13.6} \right)}{(T_m + 460)} = \text{Ft.}^3$$

2. Volume of water vapor at 70°F and 29.92" Hg, Ft.³

$$V_{wgas} = 0.0474 \times V_w = \text{Ft.}^3$$

3. % Moisture in stack gas

$$\%M = \frac{100 \times V_{wgas}}{V_{mstd} + V_{wgas}} = \%$$

4. Mole fraction of dry gas

$$M_d = \frac{100 - \%M}{100}$$

5. Average molecular weight of dry stack gas

$$M W_d = \left(\% \text{CO}_2 \times \frac{44}{100} \right) + \left(\% \text{O}_2 \times \frac{32}{100} \right) + \left(\% \text{N}_2 \times \frac{28}{100} \right)$$

6. Molecular weight of stack gas

$$M W = M W_d \times M_d + 18 (1 - M_d)$$

7. Stack velocity at stack conditions, fpm

$$V_s = 4350 \times \sqrt{\Delta P_s \times (T_s + 460)} \left(\frac{1}{P_s \times M W} \right)^{1/2} = \text{fpm}$$

8. Stack gas volume at standard conditions, SCFM

$$Q_s = \frac{0.123 \times V_s \times A_s \times M_d \times P_s}{(T_s + 460)} = \text{SCFM}$$

9. Percent isokinetic

$$\%I = \frac{1032 \times (T_s + 460) \times V_{mstd}}{V_s \times T_t \times P_s \times M_d \times (D_n)^2} = \%$$

10. Particulate - probe, cyclone and filter, gr/SCF

$$C_{an} = 0.0154 \times \frac{M_f}{V_{m std}} = \text{gr/SCF}$$

11. Particulate total, gr/SCF

$$C_{ao} = 0.0154 \times \frac{M_t}{V_{m std}} = \text{gr/SCF}$$

12. Particulate - probe, cyclone and filter, gr/CF at stack conditions

$$C_{at} = \frac{17.7 \times C_{an} \times P_s \times M_d}{(T_s + 460)} = \text{gr/CF}$$

13. Particulate - total, gr/CF at stack conditions

$$C_{au} = \frac{17.7 \times C_{ao} \times P_s \times M_d}{(T_s + 460)} = \text{gr/CF}$$

14. Particulate - probe, cyclone and filter, lb/hr.

$$C_{aw} = 0.00857 \times C_{an} \times Q_s = \text{lb/hr.}$$

15. Particulate - total, lb/hr.

$$C_{ax} = 0.00857 \times C_{ao} \times Q_s = \text{lb/hr.}$$

16. % Excess air at sampling point

$$\% \text{ EA} = \frac{(\% \text{ O}_2) - 0.5 (\% \text{ CO})}{0.264 (\% \text{ N}_2) - (\% \text{ O}_2) + 0.5 (\% \text{ CO})} \times 100$$

17. PARTICULATE EMISSIONS IN GRAINS PER STANDARD CUBIC FOOT DRY ADJUSTED TO 12% CO₂

$$\text{GR/SCFD @ 12\% CO}_2 = C_{an} \times \frac{12.0}{\text{MEASURED \% CO}_2}$$

18. PARTICULATE EMISSIONS IN POUNDS EMISSION PER 1000 POUNDS OF FLUE GAS ADJUSTED TO 50% EXCESS AIR

$$\frac{\text{LB}}{\text{C}_{50\% \text{ E.A.}}^{1000}} = 1000 \times \frac{C_{aw}}{60} \times \frac{100 + \% \text{ EA}}{150} \times \frac{387}{\text{MW}} \times \frac{\text{Md}}{Q_s}$$

VELOCITY DETERMINATION

To determine the gas velocity an "S" type pitot tube, manometer, thermocouple, and a pyrometer were employed (See Figure #5).

The probe tip was placed at each point shown in Figure #3 and the " ΔP " (differential pressure), across the front and back face of the pitot tube, is indicated by the manometer in inches of H_2O .

The probe is turned at right angles to the gas flow and one connection to the manometer is opened to atmospheric pressure. The reading in inches of water (" H_2O ") is noted as the static pressure and recorded on the Data Sheet.

The thermocouple junction reacts to the surrounding temperature by producing a voltage differential. This voltage is read out directly by a potentiometer in degrees fahrenheit ($^{\circ}F$).

VELOCITY DETERMINATION

FIGURE #5

HYDROCARBON SAMPLING

The hydrocarbon sampling train consists of (1) a heated glass probe, (2) a 3 inch coupling, (3) an aluminum box, (4) three 250 ML hydrocarbon sampling flasks. The flasks are connected to a manifold with 12/5 ball and socket joints, (5) two 350 watt strip heaters (one on the bottom of the box, the other inside the top cover), (6) a thermometer, (7) the exhaust from the box to the pump inlet. (See Figure #6.)

A sample is drawn through one flask at a time, for a minute or two. The valve on the pump end of the flask is closed first, then the valve on the probe end.

HYDROCARBONS ANALYSIS

The method used to measure the hydrocarbon sample is with a Perkin-Elmer 881 gas chromatograph with flame ionization detectors. A 1/8" blank stainless steel column at 200°C with a Perkin-Elmer lcc gas sampling loop is used to inject the sample into the detector.

The samples are heated and displaced from the flask with mercury. Standards are made up from calibrated gases using a ppm Hexane in N₂ standards.

OXIDES OF NITROGEN SAMPLING (EPA Method No. 7)

A grab sample is collected in an evacuated flask containing a dilute sulfuric acid - hydrogen peroxide absorbing solution.

The sampling procedure consists of pipetting 25 ml of H_2SO_4 - H_2O_2 absorbing solution into a 2 liter sampling flask. The flask is then evacuated to at least 3 in. Hg. absolute pressure. The next step is to evacuate the probe prior to sampling. The sample is then taken over a period of 15 seconds. After the sample has been collected, the flask is shaken for approximately 5 minutes. After this period the flask must be left with the sample for a minimum of 16 hours. After the 16 hours, the flask is reshaken for a period of two minutes. After this the final pressure of the flask is recorded and the sample is transferred to the lab for analysis. The sampling apparatus used to collect oxide of nitrogen samples is shown in Figure #7.)

NO₂ ANALYSIS

- The amount of nitrogen dioxide in the sample is determined by the phenoldisulphonic method. This method is as follows:

The sample is placed in a beaker and NaOH is slowly added until the solution is neutral or slightly basic by Litmus paper indication. This solution is then evaporated in the beaker used for neutralization. To the dry residue, two (2) milliliters of phenoldisulphonic acid are added and mixed to dampen all the precipitate. Then add two (2) milliliters of distilled water and mix thoroughly; add twenty (20) more milliliters of distilled water and mix. Add concentrated NH_4OH to this solution in excess of neutralization. Filter solution if necessary and transfer to a volumetric flask. Using a spectrophotometer at 420 Mu, compare results with a standard curve based on standard concentrations, and read milligrams of nitrogen in the sample.

NO_x SAMPLING TRAIN

FIGURE #7.

OXIDES OF SULFUR SAMPLING (EPA Method No. 6)

The sulfur oxides sampling train consists of the following components arranged and illustrated schematically (See Figure #8): (1) glass wool filter, (2) an electrically heated glass probe, (3) variac, (4,5,6,7) four midget impingers, (8) ice bath, (9) drying tube containing silica gel, (10) vacuum gauge, (11) control valve, (12) vacuum pump, (13) dry gas meter, and (14) thermometer.

The probe is made of an 18" length of medium wall Pyrex tubing wound with 26 gauge nichrome heating wire. The front end of the probe includes a two-inch long area for insertion of glass wool to be used as a filtering device. The wire is connected to a variable transformer which allows the voltage and hence the heat input to be controlled. The wire is covered with a fiberglass insulation tape.

The probe connects to a coarse frit midget bubbler containing 15 ml of 80% isopropanol, and three midget impingers, the first two of which contained 15 ml of 3% H_2O_2 each with the third left dry, connected in series. The chamber near the bubbler outlet is stuffed with fine glass wool. An ice bath is provided for the bubbler and impingers. Attached to the outlet of the third impinger is a drying tube filled with silica gel of the indicator type. A bypass valve is provided for the leakless pump and a vacuum gauge and needle valve were installed at the inlet of the pump. The dry gas meter has a sensitivity of 0.001 cubic foot and is fitted with thermometers on the meter inlet and outlet.

SO₂, SO₃ ANALYSIS

The amount of sulfur dioxide and sulfur trioxide are measured as follows:

Dilute solution used for sampling to 50 ml. Pipette 10 ml. of this solution into a 125 ml. Erlenmeyer flask. Add 40 ml. of isopropanol and two to four drops of thorin indicator. Titrate to a pink endpoint using 0.01 N barium perchlorate. Run a blank with each series of samples.

ES 056-1/74

CO₂, O₂ and CO SAMPLING AND ANALYSIS

Samples were collected by traverse through a sampling tube attached to the particulate sampling probe and aspirated into leveling bottles as illustrated in Figure #9. The gas collected was immediately tested with an Orsat apparatus for CO₂, O₂ and CO concentration.

STATE OF CONNECTICUT
DEPARTMENT OF ENVIRONMENTAL PROTECTION

STATE OFFICE BUILDING

HARTFORD, CONNECTICUT 06115

October 4, 1973

Mr. Robert Epstein
York Research Corporation
One Research Drive
Stamford, Connecticut 06906

Dear Mr. Epstein:

You are hereby notified that "Intent to Test" form No. 730082 which describes a test plan for sampling emissions from the sludge incinerator at the Willimantic Wastewater Treatment Plant, Willimantic, Connecticut, is acceptable and meets the test criteria required by the State of Connecticut, Department of Environmental Protection.

The field tests will be observed by Mr. Carl Dodge unless you are otherwise notified. He should be informed of progress and problems that may alter the test program.

Very truly yours,

Terrence DellaVecchia
Air Pollution Engineer
