Table A-1. Comparison of CA1B, KY1B-1, and KY1B-2.

Parameter	Site			
	CA1B H10	CA1B H12	KY1B-1 H5	KY1B-2 H3
Site Type	Litter on Floor			
House Ventilation Type	Mechanically-ventilated (MV) (tunnel)			
House Capacity (no. of birds per flock)	21,000 ^a		24,400 (summer) 25,800 (winter)	
Bird Type	60% Cobb, 40% Ross		100% Cobb (mixed sex)	
Average Animal residence time, days	42		53	
Frequency of full clean-out	After three flocks		Once per year	
Decaking	After each flock top 20-25% of litter removed from entire length of house		After each flock	
Manure storage in barn, days	46 (brooder area), 155 (back)		~ 365	
# buildings at site	16		8	24
Year of construction	1960s/2002		1992	1991
Ridgeline orientation	East-West		North-South	
Barn width, m	12.2 (40 ft)		13.1 (43 ft)	
Barn length, m	125 (410 ft)		155.5 (510 ft)	
Barn area, m ²	1,524 (16,400 ft ²)		621 (2,1930 ft ²)	
Barn spacing, m	12.2 (40 ft)		18.3 (60 ft)	
Ridge height, m	4.2 (13.8 ft)		5.2 (17.2 ft)	
Sidewall height, m	2.3 (7.5 ft)		2.1 (7 ft)	
Number of air inlets	60 sidewall/2 tunnel		52	
Type of inlet	Baffled eave inlet, 0.18 x 1.32 m (0.6 x 4.3 ft)		box air inlets 15 x 66 cm (6 x 26 inch)	
Inlet control basis	Static pressure		automatic	
Number of exhaust fans	12		14	
Largest fan dia., m	1.22 (48 in)		1.22 (48 in)	
Smallest fan dia., m	0.91 (36 in)		0.91 (36 in)	
Fan spacing, m	0.2 (8 in)		36.6 m (120 ft)	
Number of Ventilation Stages	17		12	13
Fan manufacturer	Choretime (48), Aerotech (36)		CanArm	Euroemme
Controls vendor	Choretime (48), Aerotech (36)		Chore-Time	Rotem
Artificial heating	LP Radiant brooders (14), 42,000 Btu/h LP heaters (3), 180,000 Btu/h		Pancake brooders (26), 30,000 Btu/h Space furnaces (3) 225,000 Btu/h	
Summer cooling	Tunnel/EP		Tunnel/EP	
Brooding section	East half of barn		South half of barn	
Monitoring Period	Sept. 27, 2007- Oct. 21, 2009		Feb. 14, 2006 – March 14, 2007	Feb. 20, 2006 – March 5, 2007
Length of Monitoring (days)	756		394	379

^a The NAEMS documentation for site CA1B did not indicate a difference in summer and winter bird placements.

Table A-2. PM Sampling Schedule CA1B.

Time and day, m/d/y		Test duration (days)

Appendix B - Data Processing

List of Tables

Table B-1. Summary of the effect of applying the negative emission cut-off to broiler data.....B-4

1.0 NEGATIVE EMISSION VALUE ASSESSMENT METHODOLOGY

Negative calculated emission values can occur in NAEMS data set due to a range of different scenarios as described in the SAB review of the 2012 EEMs developed by EPA (U.S. EPA SAB, 2013). A summary of these scenarios and whether SAB recommended the data should be retained or removed is provided below:

1. A calculation bias may occur when measured values are at or close to the detection limit, or negative. This scenario should result in small negative values, which should be retained.
2. In NAEMS, the background and source measurements were measured either intermittently (twice a day for gas), or continuously without correction for lag time in the barn (PM data), thus leading to a bias either up or down, introducing the potential for negative emission values. Negative emission values should be retained because this bias could occur in either the positive or negative direction.
3. Outdoor events may affect background and barn concentrations. For example, if there was activity outside an animal barn which resulted in increased pollutant concentration (e.g., manure cleanout of another barn), the measured background values would create a negative bias. Alternatively, a positive bias could occur if meteorological conditions caused the barn exhaust air to return into the barn, thus affecting measured barn concentrations.

To avoid bias from the true value, the SAB suggests keeping calculated values from scenario 1 and 2 and removing values identified to be caused by scenario 3, however the NAEMS did not record outdoor events that may affect background concentration (scenario 3), therefore it could not be determined if negative emissions were caused by scenario 2 or 3. It is likely that scenarios 1 and 2 result in smaller negative (closer to zero) emissions than scenario 3. Therefore, a methodology was developed to remove large negative emissions likely associated with scenario 3. In the NAEMS QAPP, the gas and PM barn emission uncertainty were determined to be $\pm 27\%$ and $\pm 32\%$ for mechanically ventilated barns and $\pm 50\%$ and $\pm 53\%$ for naturally ventilated barns (Heber et al. 2008). Cut-offs for valid negative data were therefore determined for each pollutant by multiplying the emission uncertainty by the median of the positive measured emission values.

Table B-1. Summary of the effect of applying the negative emission cut-off to broiler data.

Pollutant	Median positive emission (kg d ⁻¹ / g d ⁻¹) ^a	Uncertainty (%)	Negative emission Cut-Off (kg day ⁻¹ / g d ⁻¹) ^a	# of negative emission values		
				Before cut-off applied	Removed due to cut-off	After cut-off applied
NH ₃	11.72	27	-3.16	2	0	2
H ₂ S	32.00	27	-8.64	37	3	34
PM ₁₀	754.10	32	-241.31	4	0	4
PM _{2.5}		32	-16.29	0	0	0
TSP		32	-559.85	0	0	0

^a NH₃ emissions in units of kg d⁻¹, all other pollutants in units of g d⁻¹

1 Data Completeness Criteria for the Revised Data Set

The appropriate data completeness criteria to use in a study depends on the size of the dataset and the accuracy needed. A study by Grant et al. (2013), in which NH₃ emissions were modeled from swine lagoons based on NAEMS data, investigated data completeness and associated accuracy. The swine lagoon NH₃ emissions dataset had limited data availability at a data completeness of 75%. Grant et al. (2013) explored how much the data completeness criteria could be relaxed but still result in data with acceptable error. The study suggested an error of $\pm 25\%$ to be acceptable and determined that a daily data completeness of 52% (or 25 out of 48 30-minute periods) gave less than $\pm 25\%$ error (see Figure B-1). Using this relaxed daily completeness criteria resulted in a substantial increase in the size of the dataset.

Based on Figure B-1 from the Grant et al. (2013) study, it can be observed that a daily completeness criterion of 75% (36 out of 48 30-minute periods) would give an error of approximately 10%. If it is assumed that the relationship between data completeness and error from the Grant et al. (2013) study is representative of other NAEMS datasets, the effect of relaxed data completeness criteria can be investigated for other NAEMS sources.

The following sections examine the effect of a reduced data completeness criterion on the number of valid average daily means (ADM) for both the layer barns and manure shed, based on additional analysis completed by Heber that examined the effect of different completeness criteria by comparing the number of valid ADM.

EPA reviewed this data for the egg-layer sites and retained the 75% completeness criterion for all sites. The full analysis can be found in Appendix B.

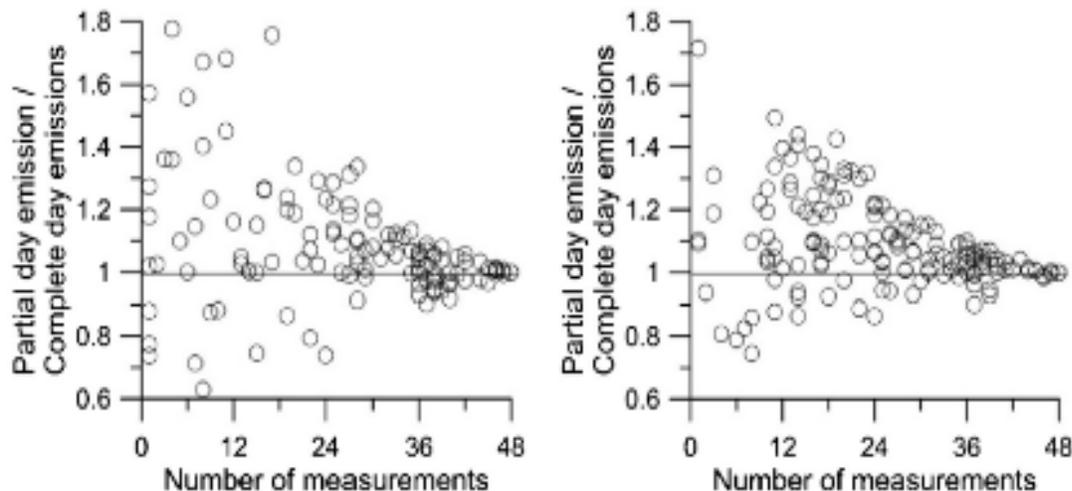

Figure C-1. Ratio of mean predicted emissions for portion of day with valid emissions measurements to mean predicted emissions for the complete day at the finishing (A) and sow (B) farm. Error plotted against number of valid 30-minute measurements (from Grant et al.

1.1 Data Completeness Review and Conclusions for the CA1B dataset

The number of average daily means (ADM) for NH₃ emissions at varying percentages of data completeness for the revised data set are shown in Figure C-1. For the Broiler site data set, decreasing the daily completeness criteria from 75% to 50% would increase the number of valid days by 32 (3%), but based on the Grant et al. (2013) study there would be an approximate 15% increase in error. Since the small increase in the number of ADM values does not justify the 15% increase in error, a daily completeness criterion of 75% was chosen for the revised NH₃ Broiler site data set.

Table C-1. The number of Broiler ADM for NH₃ at varying percentages of data completeness.

% Valid Data	0	10	20	30	40	50	60	70	75	80	90	100
CA1B H10	506	505	504	502	497	487	477	472	472	466	456	363
CA1B H12	506	505	504	502	497	488	476	473	471	466	462	389
Total	1,012	1,010	1,008	1,004	994	975	953	945	943	932	918	752

For H₂S, the number of ADM at varying percentages of data completeness for the revised data set are shown in Table C-2. For the Broiler site data set, decreasing the daily completeness criteria from 75% to 50% would increase the number of valid days by 38 (3%), but based on the Grant et al. (2013) study there would be an approximate 15% increase in error. Since the small increase in the number of ADM values does not justify the 15% increase in error, a daily completeness criterion of 75% was chosen for the revised H₂S Broiler site data set.

Table C-2. The number of Broiler ADM for H₂S at varying percentages of data completeness.

% Valid Data	0	10	20	30	40	50	60	70	75	80	90	100
CA1B H10	628	627	626	624	620	612	602	597	596	588	576	460
CA1B H12	628	627	626	624	620	614	601	596	592	585	581	490
Total	1,256	1,254	1,252	1,248	1,240	1,226	1,203	1,193	1,188	1,173	1,157	950

For PM₁₀, the number of ADM at varying percentages of data completeness for the revised data set are shown in Table C-3. For the Broiler site data set, decreasing the daily completeness criteria from 75% to 50% would increase the number of valid days by 456 (14%). The number of ADM for PM_{2.5} are presented in Table C-4, and show the number of valid ADM would increase by 5 (5%). TSP (Table C-5) had an increase of 9 days (12%), when shifting to 50% completeness criteria. Again, the small increase in the number of ADM values does not justify the 15% increase in error, a daily completeness criterion of 75% was chosen for the all the PM species for the Broiler data set.

Table C-3. The number of Broiler ADM for PM₁₀ at varying percentages of data completeness.

To further explore the trends between the predictor variables and emissions, and determine whether the parameter should be included in developing an EEM, EPA prepared scatter plots of emissions versus the process, environmental, and manure parameters and conducted least squares regression analysis to assess the influence of each variable on emissions. For the regressions, EPA classified the linear relationships based on the ranges in Table F-1.

Table F-1: Relationship classification based on R² values.

Range of R ²	Relationship strength
R ² = 0	none
0 < R ² ≤ 0.2	slight or weak
0.2 < R ² ≤ 0.4	modest
0.4 < R ² ≤ 0.6	moderate
0.6 < R ² ≤ 0.8	moderately strong
R ² > 0.8	strong

For broilers, litter age can affect emission rates in the house. To account for this, EPA tested five parameters to account for the age of the litter:

- Litter age: continuous variable that indicates the number of days since litter removal.
- Litter Status (0-1, continuous between flocks): discrete variable to indicate whether the flock was the first flock raised on fresh litter (0) or if it was not fresh litter (1). The value is held during transition periods between flocks.
- Litter Status (0-3, continuous between flocks): discrete variable to indicate the number of flocks since litter removal, where 0 indicates the first flock raised on fresh litter, up to 3 to indicate four or more flocks had been raised on the litter. The value is held during transition periods between flocks.
- Litter status (0-6, continuous between flocks): discrete variable to indicate the number of flocks since litter removal, where 0 indicates the first flock raised on fresh litter and up to 6 to indicate the up to seven (7) flock raised on the litter before a full clean out. The value is held during transition periods between flocks.
- Litter Status (0-6; empty between flocks): discrete variable to indicate the number of flocks since litter removal, where 0 indicates the first flock raised on fresh litter and up to 6 to indicate the up to seven (7) flock raised on the litter before a full clean out. The value set to “null” during transition periods between flocks.

Table F-2: Summary of high rise house R² values.
