RE: 49-00074-01-A3

Dear Messrs. Hammond and Pounds:

Please find enclosed corrections and revisions to the source test report on Halls Gin. This is in accordance with my discussions with Mr. Bob Marshall after he reviewed the report. Please replace previous pages with these insertions.

Thanks once again for your cooperation in allowing the Division of Air Pollution Control to conduct source testing at your facility. We certainly appreciate Mr. Marshall's assistance as well as the knowledge he shared with us due to his extensive background in gin operation and air pollution control design.

We also appreciate the courtesy and cooperation of Mrs. Nellie Baker and the rest of your staff.

Sincerely,

Eric R. Flowers

Dear Messrs. Hammond and Pounds:

Enclosed as an attachment to this letter is a copy of the source test report of the testing conducted by personnel of this agency on the Halls Gin Company cotton gin. This report shows that the facility was in compliance with both the currently effective process weight table for new sources and the Division's previous process weight table specific for cotton gins. This latter table is still effective at the Federal level.

If you have any questions concerning the contents of this report, please contact Mr. Carl Koontz at (615) 741-3651.

Sincerely,

Harold E. Hodges by EES

10. Gin Stand 1 Moss Condenser 3rd Stage Lint Cleaner	2,100	2,100	42 (vent)	.0078	.14

Operation Involved (Sequential)	Total Flow Rate (ft ³ /min)	Flow Rate Per Emission Point (ft ³ /min)	Cyclone or Exhaust Diameter (inches)	Average Outlet Concentration (gr/dscf)	Total Emissions (lbs/hr)
11. Gin Stand 2 Moss Condenser 3rd Stage Lint Cleaner	2,100	2,100	42 (vent)	.0064	.11
12. Gin Stand 3 Moss Condenser 3rd Stage Lint Cleaner	2,100	2,100	42 (vent)	.0032	.06
13. Mote Cyclone 9	2,500	2,500	30	.0234	.49
14. Mote Cyclone 10	2,500	2,500	30	.0116	.24
15. Mote Cyclone 11	2,500	2,500	30	.0203	.43
16. Mote Trash, Dual Cyclones 7A and 7B	2,500	1,250	30	.0354	.75
17. Battery Condenser Discharge	3,000	3,000	42 (vent)	.0085	.21
18. Waste Disposal Pile, Dual Cyclones 8A and 8B	2,500	1,250	36	.0644	1.36
Total Gin Emissions					11.11

Footnotes

1. During testing an average of 24,357 pounds per hour or 16.24 bales per hour was processed.
2. All cyclones are high efficiency with 2D-2D configuration.
3. All 3 gin stands utilized perforated drums with a hole diameter of .045 inches and 27% open area on the first and second stage of lint cleaning. This was purchased from Continental-Eagle Corporation.
4. On the third stage lint cleaners and battery condenser, 80 mesh screen was used with a wire diameter of .0055 inches and 31.4% open area.

INTRODUCTION AND OBJECTIVE

On October 25-27, 1988 the Tennessee Division of Air Pollution Control, Compliance Monitoring Program, performed a series of twenty-eight source emissions tests at Halls Gin Company, Halls, Tennessee. The points tested were the high pressure discharge points from the high efficiency cyclone (HEC, 2D-2D) collectors and the low pressure discharge points from the Moss and 16D condenser drums serving the cotton ginning facility.

The objective of these particulate emissions source tests was to aid the Division in the development of air pollution control regulations specific to the cotton ginning industry. Additionally, the testing was conducted to determine the compliance status of the cotton gin with the Division's previous regulations relating to the cotton ginning industry, which are still currently effective at the federal level.

SUMMARY OF RESULTS

Authority to regulate the emissions from cotton gins was returned to the Tennessee Division of Air Pollution Control through an amendment to the Tennessee Clean Air Act adopted by the State Legislature during the 1988 session. In the absence of any industry specific rules in the current Tennessee Air Pollution Control Regulations the particulate emissions from any cotton gin which began operation on or after April 3, 1972 would be regulated by Rule 1200-3-7-.03 (new process emission sources) and Rule 1200-3-7-.04 (limiting allowable emissions). As the Halls Gin Company cotton gin began operation for the 1988 ginning season, these rules would be presently applicable to it.

It has been determined that the cotton gin constitutes a single process emission source. During the testing of October 25-27, 1988 the total mass emissions from the cotton gin were determined to be 11.11 pounds per hour (utilizing hi-volume source testing methodology). The minimum grain loading value of 0.0026 grains per dry standard cubic foot of effluent gas was determined from Cyclone 1A on the cyclone quad serving the unloading system. The maximum grain loading value of 0.0861 grains per dry standard cubic foot of effluent gas was determined from the 16D unit of Gin Stand 2. Thus, the lower grain loading limited, contained in 1200-3-7-.04, of 0.02 grains per dry standard cubic foot of effluent gas would not be applicable to this source.

During the testing period the average process weight through the cotton gin was 24,357 pounds per hour. From this process weight rate an allowable emission rate of 16.91 pounds per hour is calculated utilizing Table 2. Thus, the cotton gin is in compliance with the applicable process emission standard.

Formerly the Tennessee Air Pollution Control Regulations contained specific standards for cotton gins. These were contained in Rule 1200-3-7-.08 of the Regulations. A copy of these standards is incorporated as a part of this report. While this standard has been deleted from the current air pollution control regulations, this deletion was never recognized by the Environmental Protection Agency and this would be the standard cited if that agency took any direct enforcement action against a Tennessee cotton gin. From Table 4 of this former regulation and based on the process weight recorded during the testing period (24,357 pounds per hour), it is calculated that the allowable emission rate from this cotton gin would be 36.55 pounds per hour. Again, the cotton gin would be in mass compliance.

COMMENTS CONCERNING THE TESTING OF CYCLONE 8B

At the conclusion of the third sample run for Cyclone 8B an accident occurred which destroyed the filter for that sample run and contaminated the probe wash.

During the compilation of this report a comparison was made between the results obtained from the testing of Cyclone 8A with the filter weight gains from the first two sample runs for Cyclone 8B.

As the data obtained for Cyclone 8B is compatible with the results obtained for Cyclone 8A and since both Cyclones 8A and 8B are part of a doublet, it was determined that the sampling results obtained for Cyclone 8A would be prorated for Cyclone 8B. The SUMMARY OF RESULTS and DATA SUMMATION portions of this report reflect this decision.

EF/F1089012

SAMPLING TRAIN COMPONENTS, METHOD OF USE, AND ANALYTICAL TECHNIQUES

A. Components

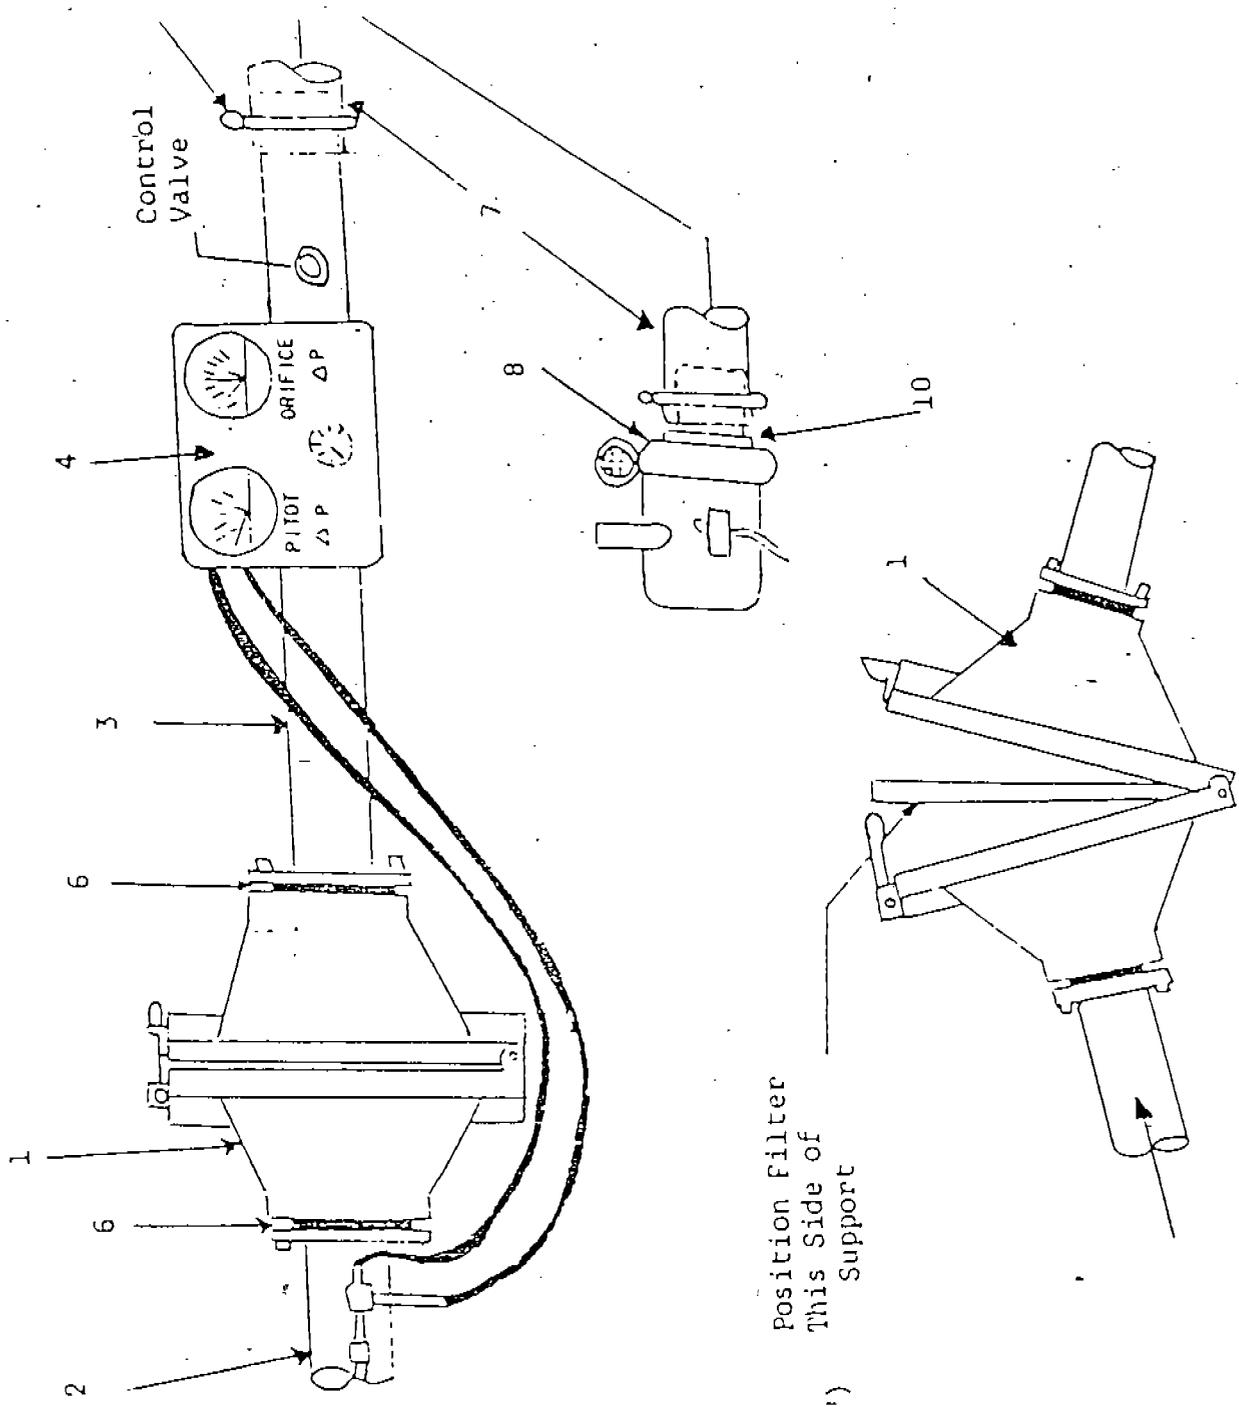

1. Aluminum probe with three nozzles. One nozzle of 15/16 inch diameter, one nozzle of 1 7/8 inch diameter, and the third nozzle of 1 1/2 inch diameter.
2. In-line filter of 0.3 micron porosity.
3. In-line orifice with pressure differential gauge of two inches water range and temperature gauge of appropriate scale.
4. Butterfly valve to control flow through sampling train.
5. Flexible hose from the train to fan.
6. Centrifugal fan.

B. General Sampling Procedure

1. Leak checks confirmed the sampling equipment was sufficiently gas tight for the tests.
2. Isokinetic sampling was accomplished using a standard pitot tube and charts that were generated from graphs provided by the sampler manufacturer.
3. When practicable, samples were taken at multiple points across the exit gas stream. Samples were taken only at points of outgoing flow and where isokinetic sampling was achievable.
4. The durations of the sampling periods depended upon the duration of operation of the process and the estimate rates of loading of the filters.
5. Moisture content of the gas stream was determined by taking the dry and wet bulb temperatures of the gas.

C. Analytical Techniques

1. Before sampling, the filters were exposed to room conditions with a humidity of less than fifty percent and allowed to reach equilibrium with the room conditions. The filters were then weighed to the nearest 0.1 mg.
2. After each sampling run, material deposited on the inside wall of the sampling probe and sampling train ahead of the filter was brushed from the probe onto the filter. After each test, a series of 3 runs, any remaining material deposited on the inside wall of the probe and filter holder was washed by acetone into a beaker and collected as probe wash. The filters were exposed to room conditions with a humidity of less than fifty percent and allowed to reach equilibrium with the room conditions. The filters were then weighed to the nearest 0.1 mg. The probe wash was transferred to a tared beaker, evaporated in an oven at 130°F, cooled in a desiccator, and weighed.

DETERMINATION OF EFFLUENT GAS MOISTURE CONTENT

The Tennessee Air Pollution Control Regulations requires that grain loadings be determined on a dry basis. Therefore, it was necessary to determine the moisture content of each exhaust gas stream sampled in order to correct the given flows to dry conditions. This was accomplished by taking a wet bulb temperature for each exhaust gas stream sampled. Then, following the saturation line of a psychrometric chart, each wet bulb temperature is matched with its corresponding moisture content. The psychrometric chart used for the moisture determinations for the testing conducted at Halls Gin Company follows this page of the report.

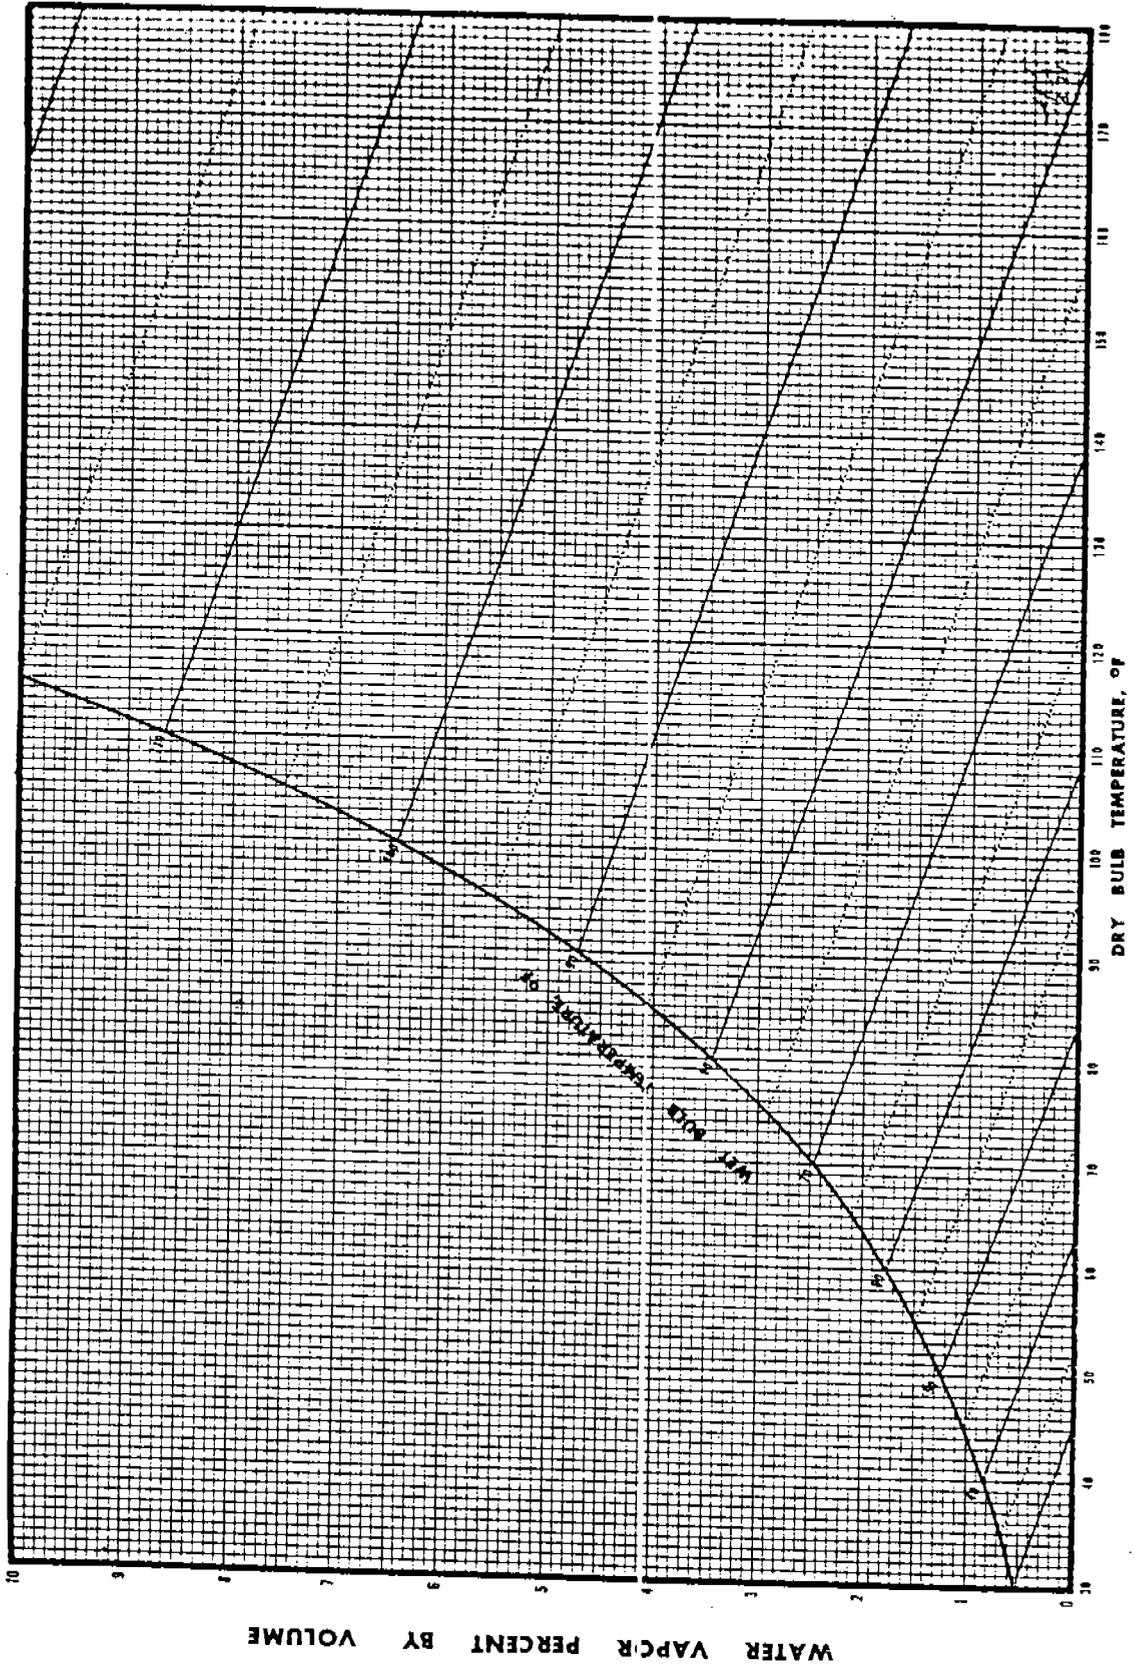

Figure D8. Psychrometric chart expressing volume of water vapor by %.

Test Dates
October 25 - 27, 1988

Eric R. Flowers

I. Gin Description

Halls Gin Company is a newly constructed cotton gin which produced its first bale of cotton early in October 1988. Mr. Tom Hammond and Mr. Miller Pounds selected gin machinery and equipment for the new gin and are in charge of gin management. Mr. Bob Marshall of Covington, Tennessee was responsible for designing the gin, selecting and installing air pollution control devices, and managing the mechanical operation during the first season. Halls Gin has a capacity to handle 7 1/2 bales per hour for each of the three gin stands for a total capacity of 22 1/2 bales per hour. The location of the gin is in the Halls Industrial Park in Lauderdale County, just northwest of Halls and about 10 miles south of Dyersburg.

II. Process Description

A. Layout and Flow Diagram

Figure 1 depicts the layout of Halls Gin Company showing operations and equipment. Figure 2 is a flow diagram of how the cotton is ginned, tracing basic steps which include unloading of raw cotton, drying, cleaning, related processing, and baling of the cotton (the final product). The flow pattern of handling trash, byproducts, and emissions to the atmosphere is also depicted. Figure 3 is a diagram of the emission points at the gin.

B. Composition of Cotton

Cotton processed at Halls Gin Company is picker harvested cotton. This is a taller plant than the western "stripper-harvested" variety. A spindle picker harvests the cotton by removing cotton from the bur with rotating spindles, leaving unopened bolls on the plant and collecting fewer amounts of leaves, burs, and trash than stripper cotton.

Spindle picked cotton has the following approximate composition for a typical 1500 pound load.

<u>Component</u>	<u>Weight (lbs)</u>	<u>Weight Percent (%)</u>
Seed	800	53.3
Lint Cotton (bale)	495	33.0
Trash	158	10.5
Moisture	25	1.7
Motes	22	1.5
Total	1500	100.0

As can be seen from the above analysis, a 495 pound bale of lint cotton is recovered from 1500 pounds of spindle picked cotton. The above composition may vary especially due to actual trash content and moisture content. Besides lint cotton there are two other basic byproducts. Seed is sold as a separate product. Motes, which are basically immature seeds, are cleaned, baled, and sold for use as upholstery stuffing.

C. Process Operations

The purpose of a cotton gin is to separate cotton fibers (lint) from the cotton seed and to remove the trash from the lint. This is an essential function before cotton will be acceptable for use in the textile industry.

At Halls Gin Company this is accomplished in the following sequential manner.

1. Weighing and Unloading Stations

Trailers are previously weighed or weighed at the scale house without a load. The loaded trailer (gross weight) is then recorded and the difference in weight (tare weight) represents the weight of cotton. The loaded trailers are ticketed and brought into a two lane bay area inside the gin building. Here one trailer at a time is unloaded by means of a manually operated telescoping suction pipe (suck pipe). The number of bales of cotton per trailer load is typically between 6-14 and the time to unload a trailer varies normally between 25 to 58 minutes depending on operator ability, load size, and mechanical problems in the gin. Modules of cotton which have a protective covering are also unloaded in the bay area. Raw cotton is exhausted through the suction pipe to a 72 inch dual separator and feed control unit. The screen in the separator removes seed cotton from the conveying air allowing the cotton to fall into the feed control unit. Air and trash from the separator are exhausted to a quad cyclone unit consisting of Cyclones 1A, 1B, 1C, and 1D. The feed control unit functions to prevent choking in the seed cotton cleaners, evenly distributes cotton to the dryers and cleaners, and helps minimize time loss between bales.

2. Seed Cotton Cleaning System

A split tower dryer (primary drying system) unit receives seed cotton (cotton with seed intact) from the feed control unit. These 52 inch Murray dryers are heated by natural gas. Ideally, cotton is dried between 6.5 to 8.0% moisture. At Halls Gin the moisture content is typically 7 to 7.5%.

From the primary dryers, cotton is sent to two parallel systems of 72 inch inclined cleaners and stick and green leaf machines. Inclined Cleaner 1A and Stick Machine 1A are in parallel with Inclined Cleaner 1B and Stick Machine 1B. The inclined seed cotton cleaners open up the cotton and break up large clumps of cotton and then remove fine particle trash consisting of sand, dirt, and miscellaneous trash. From the inclined cleaners the seed cotton is further cleaned by an extractor or stick and green leaf machine. Centrifugal force from high-speed saw cylinders spin off large trash including sticks, stems, and burs from seed cotton. Fiber is retained on the saw. Air and

trash from Inclined Cleaner 1B and Stick Machine 1B and from Inclined Cleaner 1A and Stick Machine 1A are exhausted to dual Cyclones 2A and 2B and Cyclones 3A and 3B, respectively.

Seed cotton is further dried in a secondary tower dryer system (52 inch Murray dryers) before routing to two parallel sets of inclined and impact cleaners. Cotton from the 1A system is sent to Inclined Cleaner 2A and Impact Cleaner 2A while 1B cotton is sent to Inclined Cleaner 2B and Impact Cleaner 2B. The 72 inch impact cleaners release the seed cotton to a 14 inch conveyor distributor. Seed cotton is then evenly distributed among three extractor-feeders routing seed cotton to each of three gin stands. Dual Cyclones 4A and 4B and dual Cyclones 5A and 5B handle air and trash from Inclined Cleaners 2B and 2A respectively.

3. Overflow System

When the flow of seed cotton from the conveyor distributor exceeds that able to be received from the gin stands, excess cotton is bypassed to an overflow hopper system. Seed cotton from the overflow hopper is pneumatically conveyed to a 50 inch separator returning seed cotton to the conveyor distributor. Cotton is then fed by extractor-feeders to the gin stands as needed.

Air and trash from the overflow separator, impact cleaners, extractor-feeders, and gin trash are routed to large dual Cyclones 6A and 6B.

4. Lint Cotton Handling System

The conveyor distributor apportions cotton to each of three parallel Continental 141 gin stands by means of three extractor-feeders. Each gin stand has a capacity of 7 1/2 bales per hour. The gin stand is the heart of the gin and utilizes the original basic ginning principle invented by Eli Whitney, the spiked tooth gin. Saw teeth pass between gin ribs. Fibers are pulled from the seed rather than cut since the leading edge of the saw teeth is parallel to the rib.

Cotton enters each gin stand system through a huller front where secondary cleaning occurs. The saws hold and draw out the cotton through widely spaced huller ribs causing hulls and sticks to fall out of the machine. Cotton locks are then drawn to the bottom of a roller box from the huller ribs.

The ginning process separating the lint and seed occurs in the roll box. After seeds are cleaned (fibers removed), they slide down the gin ribs and fall into a 6 inch seed line. Seeds are pneumatically conveyed from a vacuum box to a seed storage house. Lint cotton (seed cotton no longer exists at this stage) from the saw is removed by brushes known as doffing.

From here lint cotton is conveyed to a condenser screen drum that forms a lint batt. The batt is then fed to the first set of saw lint cleaners. Saws transport cotton over grid bars and combined with centrifugal force remove immature seeds with short immature fibers (motes) and comb the lint removing leaf particles, grass, and other foreign matter. Cleaned lint is taken off the saw by a rotating brush which also provides air to convey the lint to the second stage lint cleaner. Continental Sixteen D (16D) 66 inch 4C units are used at Halls Gin on the first and second stage lint cleaners. Lint is further cleaned by a third stage lint cleaner. Gin Stands 1 and 3 have 66 inch Continental units with Moss condensers as third stage lint cleaners. Gin Stand 2 is a Constellation unit. Eighty (80) mesh wire cloth cover all three Moss condenser drums. The 16D perforated drums have .045 inch diameter holes.

The first and second stage lint cleaners from the three gin stands vent lint fly and fine dust to three separate low pressure 26 inch diameter goose-necked exhaust vents. Similarly, the three Moss condensers vent emissions to three separate 42 inch diameter vents.

5. Mote System

Motes from all three stages of lint cleaning from each gin stand are pneumatically conveyed from three lines to three separate mote cyclones identified as Cyclones 9, 10, and 11. A common hopper serves these three cyclones. A single line from the hopper transports motes to the mote cleaner. A hopper under the cleaner collects trash from the motes, roughly 50% of the material, and returns it to Cyclones 7A and 7B at the main cyclone bank. Cleaned motes are then compressed in the mote press and baled as a product ready for shipping.

6. Battery Condenser and Bale System

Lint after being cleaned from the three stages of lint cleaners is blown through a trunk-line to a 54 inch Moss battery condenser. The condenser drum is covered with 80 mesh screen to minimize emissions. A single 42 inch diameter goose-necked vent serves this low pressure exhaust. The slow turning screened drum forms a lint batt which is routed between doffing rollers to a lint slide. The slide feeds the lint batt to a baling press, packing the lint cotton in a bale ready for shipment. Bales during the days of observation ranged in weight between 448 and 514 pounds.

7. Waste Disposal System

The main cyclone bank (cyclone sets 1 through 7) discharge trash and heavy material from the base trough of the cyclones to a trash fan. This fan blows the waste to dual Cyclones 8A

and 8B above a waste disposal pile. Waste from these two cyclones is emptied to a screw conveyor which discharges the material to a waste pile about 15 feet above the ground. Two spray nozzles direct water to the cotton trash as it is augered on top of the pile. This further reduces emissions to the atmosphere.

III. Process Weight Rate and Field Notes

The following weights of raw cotton were recorded during the periods of emission testing.

<u>Date of Testing</u>	<u>Time</u>	<u>Total Weight (lbs)</u>	<u>Elapsed Time (hrs)</u>	<u>Process Weight Rate (lbs/hr)</u>	<u>Bales/Hour @ 1500 lbs. per Bale</u>
10/25/88	9:46 AM - 1:47 PM	93,060	4 1/60	23,168	15.45
10/26/88	8:46 AM - 5:15 PM	212,640	8 29/60	25,066	16.71
10/27/88	7:46 AM - 3:24 PM	189,590	7 38/60	24,837	16.56

The average process weight rate during the three days of testing calculated to be 24,357 lbs/hr or 16.24 bales per hour.

The above values were determined by utilizing weight tickets for each trailer load and timing the beginning and end of the loading as close as possible to the actual stack emission testing periods.

A random check of bale press times was made. The following times were measured at the bale press station.

<u>Time to Form One Bale (minutes and seconds)</u>	<u>Bales Per Hour</u>
3:50	15.65
2:50	21.18
3:22	17.82
3:30	17.14

This averages to be 17.94 bales per hour and is reasonably close to long range weight measurement over the three day period.

During actual operation it is not uncommon to observe periods of delay at the suction pipe due to mechanical problems in the gin machinery. In some cases, the suction pipe operator could not continue the unloading of the trailer. These delays were normally a few minutes.

Specific timed periods to unload the following various sized trailer loads were recorded.

<u>Number of Bales in Trailer Load</u>	<u>Minutes to Unload by Suction Pipe</u>	<u>Bales Per Hour</u>
7	25	16.80
	29	14.48
9	30	18.00
	32	16.88
	35	15.43
11	42	15.71
	45	14.66
	45	14.66
12	37	19.46
13	38	20.53
	58	13.45
14	46	18.26

This averages to be 16.53 bales per hour which is very close to the average of three days of testing of 16.24 bales per hour.

With regard to gin operation during testing, the first stage lint cleaner on Gin Stand 1 was out of commission the entire period of testing. According to gin operator Bob Marshall, this was believed to have little effect on the emissions since further stages of lint cleaning performed adequately.

IV. Factors Affecting Emissions

Spindle picked cotton, as stated previously, has much less trash than the machine stripper harvested variety. The typical composition of trash in spindle picked cotton is as follows:

<u>Trash Component</u>	<u>Weight Percent of Total Trash (%)</u>	<u>Weight Per 1500 Pound Load (lbs)</u>
Leaves and Dirt	50	79.0
Burs	35	55.3
Stick	15	23.7
Total Trash	100	158.0

Raw cotton varies locally in trash content and resulting bales of lint cotton ranged in weight between 448 and 514 pounds indicating varying trash and moisture content.

The cotton gin emissions measured represented normal gin emissions because this was a first harvest. Second harvest cotton contains more foreign material. Thus, the resulting emissions did not represent the worst case emissions of the season.

Because the ginning operation uses pneumatic methods to handle seed cotton, lint cotton, cotton seeds, and trash, the conveyed material must be physically separated from the air at various stages of operation.

Emissions are enhanced due to air flow from the high pressure system (cyclones) and numerous fans on the low pressure exhaust vents (condensers, lint cleaners, etc). Emissions from cyclones serving the unloading station, inclined cleaners, stick machines, overflow system, and trash fan are primarily dust and fine leaf trash. Emissions from the gin stand, lint cleaners, mote fan, and battery condensers contain lint fly and cotton dust. Additionally, cotton dust contains some amounts (less than 1%) of pesticides, defoliant, and dessicants. DEF is a typical defoliant used for cotton in West Tennessee.

With respect to various phases of operation the uncontrolled estimated emission factors obtained in EPA's emission factor publication AP-42 can be compared to actual controlled emissions measured during testing. The chart below reflects the findings.

Operation	AP-42	Uncontrolled	Actual		Control Efficiency (%)
	Uncontrolled Emissions (lbs/bale)	Emissions Prorated in (lbs/hr)	Emissions (lbs/hr)	Emissions (lbs/bale)	
Unloading fan	5.0	81.20	.26	.016	99.7
Cleaners and dryers	.3				
Stick Machines	.2				
Total	.5	8.12	1.56	.096	80.8
Miscellaneous (including trash fan, overflow fan, lint cleaners, mote fan, and battery condenser)	1.5	24.36	9.29	.572	61.9
Total for gin	7.0	113.68	11.11	.684	90.2

Unfortunately due to manpower and time constraints, individual uncontrolled emissions for each operation were not measured. This would have involved sampling inlet concentrations prior to cyclone control on high pressure exhausts. Concentrations measurements prior to low pressure exhaust control would have been more difficult to sample. All duct and locations of lint and dust entry points before cleaning would have to be pinpointed and sampled to obtain precleaning values on the low pressure system. The above uncontrolled emissions were utilized from previous test data compiled by EPA. Process operations were ranked in order of the magnitude of pounds per hour released to the atmosphere after controls.

<u>Operation Involved</u>	<u>Emission Rate lbs/hr</u>
1. Gin Stand 2 16D Condenser Lint Cleaners, 1st and 2nd Stage	2.05
2. Gin Stand 1 16D Condenser Lint Cleaners, 1st and 2nd Stage	1.92
3. Waste Disposal Pile, Dual Cyclones 8A and 8B	1.36
4. Gin Stand 3 16D Condenser Lint Cleaners, 1st and 2nd Stage	1.04
5. Mote Trash, Dual Cyclones 7A and 7B	.75
6. Inclined Cleaner 1B and Stick Machine, Dual Cyclones 2A and 2B	.59
7. Overflow Separator, Conveyor Distributor, Impact Cleaners, Extractor-Feeders, and Gin Stand Trash, Dual Cyclones 6A and 6B	.49
8. Mote Cyclone 9	.49
9. Mote Cyclone 11	.43
10. 2A Inclined Cleaner, Dual Cyclones 5A and 5B	.38
11. 1A Inclined Cleaner and Stick Machine, Dual Cyclones 3A and 3B	.36
12. Unloading Pipe, Quad Cyclones 1A, 1B, 1C, and 1D	.26
13. Mote Cyclone 10	.24
14. 2B Inclined Cleaner, Dual Cyclones 4A and 4B	.23
15. Battery Condenser Discharge	.21
16. Gin Stand 1 Moss Condenser 3rd Stage Lint Cleaner	.14
17. Gin Stand 2 Moss Condenser 3rd Stage Lint Cleaner	.11
18. Gin Stand 3 Moss Condenser 3rd Stage Lint Cleaner	.06
Total	11.11

It should be noted that significant amounts of fine dust are released from the first and second stage lint cleaners. The 16D perforated condenser drums are used on these emission points. According to gin literature, for every bale of cotton processed, the first stage of lint cleaning removes about 20 pounds of lint and foreign matter, the second stage 10 pounds, and the third stage 6 pounds. Thus, when comparing emissions combined from the first and second stage which vent to a single exhaust to that of the third stage exhaust, the third stage emissions were found to be between 5-7% of that emitted from the first and second stage. This exceeds expectations of emission reductions estimated to be 20% (6/30 ths) of the previous stages. Thus, 80 mesh screen coverings on the Moss condenser units apparently do a better job in removing lint than the 16D perforated drums. This appears to be due in part to the smaller hole size of the 80 mesh screen which is able to filter finer sized particles resulting in a higher collection efficiency.

The overall collection efficiency of Halls Gin can be determined by comparing total gin emissions and bales per hour processed during testing to the EPA uncontrolled emission factor of 7 lbs. per bale of cotton. This is calculated as follows:

Actual Emissions:

$$\frac{11.11 \text{ lbs/hr}}{16.24 \text{ bales/hr}} = .68 \text{ lbs/bale}$$

Overall Control Efficiency:

$$\frac{7 - .68}{7} = \frac{6.32}{7.00} = 90\% \text{ control}$$

This represents very good control in comparison to typical existing gins.

V. Air Pollution Control Equipment and Techniques

Each stage of the ginning process releases its own magnitude and type of emissions. Some phases of the operation differ significantly in the amount of uncontrolled emissions. Due to the conveying and fan requirements, the air flow volume will also vary somewhat.

As has been stated, cyclones handle the high pressure exhaust. Large particles consisting of trash and dust are efficiently collected by cyclone collectors.

The cyclones at Halls Gin are small diameter, high efficiency cyclones (HEC) due to the pencil shaped configuration. The ratio of the cone length to cyclone diameter is 2:1. The body length to cyclone diameter is also 2:1. This is known as the original Atomic Energy Commission design or 2D/2D cyclone design. This is shown in Figure 4 and is the preferred design in the Cotton Ginners' Handbook. A collection efficiency greater than 99.8% by weight has been obtained for this type of cyclone design for particles above 125 um. Cotton trash is practically 100% above 30 um diameter size thus, a high collection efficiency is expected.

Most of the low pressure exhaust system utilize fine mesh screen cover on condenser drums to minimize emissions. Standard 80 mesh stainless steel wire is used to cover the three Moss third stage lint cleaners. This wire cloth is durable fine mesh screen and does not tear or develop holes as easily as the finer 100 mesh which has a smaller wire diameter. Also, back pressure which jams batts of cotton occurs more frequently with 100 mesh screen. Many ginners prefer 80 mesh over the 100 mesh because of these reasons. Eighty (80) mesh is also used on the battery condenser. The 80 mesh utilized at Halls Gins has a wire diameter of .0055 inches with a 31.4% open area. This particular screen size and wire gauge has been reported to tear less often than other grades of 80 mesh and is reliable according to people who have installed this grade in cotton gins.

The first and second stage lint cleaners utilize perforated metal drums on the Sixteen D units. These have .045 inch diameter holes with a 27% open area. There are 169 holes per square inch. This 20 gauge galvanized steel was purchased from Continental Eagle Corporation of Prattville, Alabama.

The short fiber and fine lint fly from condensers are sometimes the source of complaints of residents and gin workers. The lint fly settles on nearby structures and can be a housekeeping and respiratory nuisance. For this reason, it is quite important to utilize fine mesh screen over condensers. This is accomplished by using the 80 mesh screen at Halls Gin.

The waste disposal pile is a well managed pile. In addition to the dual cyclone system above the pile, two spray nozzles direct a mist on waste as it is augered on to the pile. Wetted material reduces the airborne fine dust from the pile and helps minimize the possibility of complaints of blowing pile dust.

(Note 1)

The rate of air flow through the orifice is precalculated for all pressure drops across the orifice using the various nozzles for an orifice temperature of 60°F. This figure is then converted to the actual air flow at the orifice temperature by the equation:

$$SR = \frac{(SR60) (T_o = 460)}{520}$$

Where: $SR60$ = sampling rate through orifice at 60°F
 T_o = average temperature of orifice (°F)

(Note 1)

The rate of air flow through the orifice is precalculated for all pressure drops across the orifice using the various nozzles for an orifice temperature of 60°F. This figure is then converted to the actual air flow at the orifice temperature by the equation:

$$SR = \frac{(SR60)(T_o = 460)}{520}$$

Where: SR60 = sampling rate through orifice at 60°F
 T_o = average temperature of orifice (°F)

CALCULATION OF ACTUAL EMISSIONS

HALLS GIN COMPANY (49-00074)

Source Identification 1B Inclined Cleaner Cyclone 2A
 Test Date Oct. 26, 1988

Q = actual airflow in ft³/min* 2,750

T_d = dry bulb temperature at exhaust point 120°F

T_w = wet bulb temperature at exhaust point 98°F

M = percent moisture in exhaust gases 6.1%

P_{bar} = barometric pressure 29.89

$$Q_{std} = (Q) \left(1 - \frac{M}{100}\right)$$

2,582

Q_{std} in dry standard ft³/min

* Based on fan data obtained from the designer and builder of the gin. The fan data is at ambient temperature, which is approximately 70° F. Barometric pressures measured during the testing were within one percent of 29.92 in. of Hg. Therefore, the given flows are considered to be at standard conditions.

(Note 1)

The rate of air flow through the orifice is precalculated for all pressure drops across the orifice using the various nozzles for an orifice temperature of 60°F. This figure is then converted to the actual air flow at the orifice temperature by the equation:

$$SR = \frac{(SR60)(T_o = 460)}{520}$$

Where: SR60 = sampling rate through orifice at 60°F
 T_o = average temperature of orifice (°F)

CALCULATION OF ACTUAL EMISSIONS

HALLS GIN COMPANY (49-00074)

Source Identification 2A Inclined Cleaner Cyclone 5A
 Test Date Oct. 26, 1988

Q = actual airflow in ft³/min* 2,250

T_d = dry bulb temperature at exhaust point 117°F

T_w = wet bulb temperature at exhaust point 99°F

M = percent moisture in exhaust gases 6.3%

P_{bar} = barometric pressure 29.89

$$Q_{\text{std}} = (Q) \left(1 - \frac{M}{100}\right)$$

2,108

Q_{std} in dry standard ft³/min

* Based on fan data obtained from the designer and builder of the gin. The fan data is at ambient temperature, which is approximately 70° F. Barometric pressures measured during the testing were within one percent of 29.92 in. of Hg. Therefore, the given flows are considered to be at standard conditions.

(Note 1)

The rate of air flow through the orifice is precalculated for all pressure drops across the orifice using the various nozzles for an orifice temperature of 60°F. This figure is then converted to the actual air flow at the orifice temperature by the equation:

$$SR = \frac{(SR60) (T_o = 460)}{520}$$

Where: SR60 = sampling rate through orifice at 60°F
 T_o = average temperature of orifice (°F)

CALCULATION OF ACTUAL EMISSIONS

HALLS GIN COMPANY (49-00074)

Source Identification Cotton Waste Disposal Cyclone 8BTest Date Oct. 27, 1988Q = actual airflow in ft³/min* 1,250T_d = dry bulb temperature
at exhaust point 78°FT_w = wet bulb temperature
at exhaust point 62°FM = percent moisture in
exhaust gases 1.9%P_{bar} = barometric pressure 29.77

$$Q_{\text{std}} = (Q) \left(1 - \frac{M}{100}\right)$$

1,226Q_{std} in dry standard ft³/min

* Based on fan data obtained from the designer and builder of the gin. The fan data is at ambient temperature, which is approximately 70° F. Barometric pressures measured during the testing were within one percent of 29.92 in. of Hg. Therefore, the given flows are considered to be at standard conditions.

CALCULATION OF ACTUAL EMISSIONS

HALLS GIN COMPANY (49-00074)

Source Identification Mote Press Cyclone 10
 Test Date Oct. 27, 1988

Q = actual airflow in ft³/min* 2,500

T_d = dry bulb temperature at exhaust point 86° F

T_w = wet bulb temperature at exhaust point 67° F

M = percent moisture in exhaust gases 2.2%

P_{bar} = barometric pressure 29.67

$$Q_{\text{std}} = (Q) \left(1 - \frac{M}{100}\right)$$

2,445

Q_{std} in dry standard ft³/min

* Based on fan data obtained from the designer and builder of the gin. The fan data is at ambient temperature, which is approximately 70° F. Barometric pressures measured during the testing were within one percent of 29.92 in. of Hg. Therefore, the given flows are considered to be at standard conditions.

(Note 1)

The rate of air flow through the orifice is precalculated for all pressure drops across the orifice using the various nozzles for an orifice temperature of 60°F. This figure is then converted to the actual air flow at the orifice temperature by the equation:

$$SR = \frac{(SR60)(T_o = 460)}{520}$$

Where: SR60 = sampling rate through orifice at 60°F
 T_o = average temperature of orifice (°F)

CALCULATION OF ACTUAL EMISSIONS

HALLS GIN COMPANY (49-00074)

Source Identification Battery Condenser Vent
 Test Date Oct. 27, 1988

Q = actual airflow in ft³/min* 3,000

T_d = dry bulb temperature
 at exhaust point 80°F

T_w = wet bulb temperature
 at exhaust point 70°F

M = percent moisture in
 exhaust gases 2.5%

P_{bar} = barometric pressure 29.67

$$Q_{std} = (Q) \left(1 - \frac{M}{100}\right)$$

2,925

Q_{std} in dry standard ft³/min

* Based on fan data obtained from the designer and builder of the gin. The fan data is at ambient temperature, which is approximately 70° F. Barometric pressures measured during the testing were within one percent of 29.92 in. of Hg. Therefore, the given flows are considered to be at standard conditions.

Company Halls Gin Co.Test Date Oct. 27, 1988Cyclone I.D. Battery Condenser Vent

(Note 1)

The rate of air flow through the orifice is precalculated for all pressure drops across the orifice using the various nozzles for an orifice temperature of 60°F. This figure is then converted to the actual air flow at the orifice temperature by the equation:

$$SR = \frac{(SR60)(T_o = 460)}{520}$$

Where: SR60 = sampling rate through orifice at 60°F
 T_o = average temperature of orifice (°F)

(Note 1)

The rate of air flow through the orifice is precalculated for all pressure drops across the orifice using the various nozzles for an orifice temperature of 60°F. This figure is then converted to the actual air flow at the orifice temperature by the equation:

$$SR = \frac{(SR60)(T_o = 460)}{520}$$

Where: $SR60$ = sampling rate through orifice at 60°F
 T_o = average temperature of orifice (°F)

(Note 1)

The rate of air flow through the orifice is precalculated for all pressure drops across the orifice using the various nozzles for an orifice temperature of 60°F. This figure is then converted to the actual air flow at the orifice temperature by the equation:

$$SR = \frac{(SR60)(T_o = 460)}{520}$$

Where: SR60 = sampling rate through orifice at 60°F
 T_o = average temperature of orifice (°F)

PERSONNEL DATA

DATES OF SOURCE TEST: October 25-27, 1988

LOCATION OF SOURCE TEST: Halls Gin Company
Halls, Tennessee

PERSON IN CHARGE: Carl Koontz

PERSONNEL CONDUCTING THE SAMPLING:

Carl Koontz, Fred Singleton, Jeryl Stewart, Elizabeth Troup, Alvin Pratt,
Vicki Lowe, & Mike Hale

IDENTIFICATION OF PERSONNEL SAMPLING VARIOUS EMISSION POINTS:

Fred Singleton, Jeryl Stewart - Cyclones 1A & 1B

Fred Singleton, Mike Hale - Cyclones 3A, 3B, 4A, 4B, 5A, 5B, 6A, 6B, 7A,
7B, 8A, 8B, 10, & 11

Jeryl Stewart, Alvin Pratt - Cyclones 1C, 1D, 2A, 2B, 9, Gin Stand 1
(Moss and 16D), Gin Stand 2 (Moss and 16D), Gin Stand 3 (Moss and 16D),
and Battery Condenser

IDENTIFICATION OF PERSONNEL RECOVERING SAMPLES AND RESETTING

SAMPLING TRAINS: Elizabeth Troup, Vicki Lowe

PERSON COORDINATING VARIOUS ACTIVITIES: Carl Koontz

PERSON OBSERVING THE OPERATION OF THE PROCESS DURING THE TESTING:
Eric Flowers

SOURCE SAMPLING CHAIN OF CUSTODY DOCUMENTATION
RADER HIGH VOLUME FILTER ISSUANCE FROM LABORATORY

Rader High Volume filters Nos. 001594 - 1740 issued to Compliance Monitoring Section on OCTOBER 21, 1988 (date) by Nancy L. Flatt (laboratory person ~~preweighing filters~~). These were received by Katherine E. Trapp (Compliance Monitoring Section person receiving filters) on OCTOBER 21, 1988 (date). These filters are maintained in a secure area under the custody of the Compliance Monitoring Section supervisor until their useage in the field.

SET I. SMALL

Nozzle identification no. SET II SMALL Calibrated by FW Sjt

Date	D_1 , in., (mm)	D_2 , in., (mm)	D_3 , in., (mm)	ΔD , in., (mm)	D_{avg} in., (mm)
10/24/88	1.117	1.116	1.116	0.001	1.116
10/24/88	0.937	0.938	0.936	0.002	0.937

where:

$D_{1,2,3}$ = Three different nozzle diameters, in., each diameter measured to nearest 0.0001 in.

ΔD = Maximum difference between any two diameters, in.,
 $\Delta D \leq 0.004$ in.

D_{avg} = Average of D_1 , D_2 , and D_3 .

Note: Nozzles must be recalibrated after any visible damage and/or repairs. Knife edge must be free of nicks or dents ≥ 0.004 in.

D. COTTON GINS (New & Existing)

1. No person shall cause or permit the emission of particulate matter in any one hour from any cotton gin operation in excess of the amount shown in Table 4 for the process weight per hour allocated to such operation. Particulate matter emissions subject to this Part include process emissions and wigwam or incinerator emissions if any; provided, however, that this shall in no way relieve or affect the application of Chapters IV, V, and VI to cotton gin operations.
2. Where the nature of any process or operation or the design of any equipment is such as to permit more than one interpretation of this Part, the interpretation that results in the minimum value for allowable emission shall apply.
3. For purposes of this Part, the total process weight from all similar process units at a plant or premises shall be used for determining the maximum allowable emission of particulate matter that passes through a stack or stacks.
4. The owner or operator of a cotton gin which was in operation or under construction prior to January 1, 1973, shall meet the standards of this subsection by July 1, 1975. The owner or operator of a cotton gin on which construction begins after January 1, 1973, shall meet the standards of this subsection at the time the operation of such gin commences.

TABLE 4 ALLOWABLE PARTICULATE MATTER EMISSION BASED ON PROCESSWEIGHT RATE FOR COTTON GINS

<u>Process Wt. Rate (lb/hr)</u>	<u>Allowable Emission Rate (lb/hr)</u>	<u>Process Weight Rate (lb/hr)</u>	<u>Allowable Emission Rate (lb/hr)</u>
1,000	1.6	9,000	13.7
1,500	2.4	10,000	15.2
2,000	3.1	12,000	18.2
2,500	3.9	14,000	21.2
3,000	4.7	16,000	24.2
3,500	5.4	18,000	27.2
4,000	6.2	20,000	30.1
5,000	7.7	30,000	44.9
6,000	9.2	40,000	59.7
7,000	10.7	50,000	64.0
8,000	12.2	60,000 or more	67.4

The emission rate for a cotton gin intermediate between those shown on Table 4 shall be determined by linear interpolation.
