1. SUMMARY

1.1 BACKGROUND

This source category survey report presents information on animal feed dryers, particulate matter emissions, and control equipment in the following Standard Industrial Classification (SIC) Codes:

SIC 2046--Wet Corn Milling

SIC 2047--Dog, Cat, and Other Pet Food

SIC 2048--Alfalfa Dehydrator segment only

SIC 2063--Beet Sugar

SIC 2075--Soybean Oil Mills

SIC 2077--Animal and Marine Fats and Oils

SIC 2082--Malt Beverages

SIC 2085--Distilled, Rectified, and Blended Liquors

Of the above categories, only SIC 2047 (Dog, Cat, and other Pet Food) and SIC 2048 (Alfalfa Dehydrators) produce animal feed as a primary product; the remaining industries produce residuals or byproducts which are dried for sale as animal feed. Information from numerous sources on production, growth, industry structure, and emissions formed the basis for the estimates given in this report. The purpose of these estimates is to allow assessment of the need for a new source performance standard. Therefore, the estimates should not be used for purposes other than intended. Table 1-1 presents estimates made from available information on the number of plants, volume of production, growth trends, level of control, and annual national emissions expected from new, modified, and reconstructed facilities in the source category. Emission data obtained from State and local control agencies, industry representatives, and equipment vendors are summarized in Table 7-1 (Chapter 7).

TABLE 1-1. SOURCE CATEGORY SUMMARY^a

Industry segment	Current size (1980)			Estimated growth annual %	New/modified/reconstructed facilities (1985)			Annual emissions from new/modified/reconstructed facilities (1985)		
	Plants	Dryers	Production ^b 10 ³ Mg/yr (10 ³ tons/yr)		Plants	Dryers	Production 10 ³ Mg/yr (10 ³ tons/yr)	Uncontrolled Mg/yr (tons/yr)	Controlled Mg/yr (tons/yr)	Reduction potential Mg/yr (tons/yr)
Soybean oil mills	121	230	22,680 (25,000)	5	0	56	6,350 (7,000)	4,763 (5,250)	1,905 (2,100)	2,858 (3,150)

^aMRI estimates from available data.^bMg/yr = megagrams per year.^cEstimated reduction potential achievable with application of an emission control device on the animal feed dryer.

1.2 INDUSTRY AND PROCESS DESCRIPTIONS

The drying process in the production of animal feed involves reducing the moisture content of a product to make it suitable for further processing, storage, and use as an animal feed. Numerous types of dryers are available for drying animal feed ingredients: direct-fired rotary, steam-tube rotary, tunnel or conveyor, flash, and ring dryers. In 1980, approximately 32×10^6 megagrams (Mg) (35×10^6 tons) of dried animal feeds were sold in the United States.¹ Animal feeds may be divided into four general categories: "oilseed meal," "grain protein feeds," "animal proteins," and "other."

1.2.1 Oilseed Meal

Oilseed meal, which represents the largest industry in the source category, both in terms of production and emissions, includes meal produced at soybean oil mills. Oil is extracted from soybeans by pressing or solvent extraction, and the remaining meal is dried in steam-tube rotary dryers and sold for use as a high protein animal feed. Other oilseed meals (approximately 1 percent of soybean production) are also used for animal feed but the use of dryers is not a uniform practice in these industries. Soybeans accounted for approximately 23×10^6 Mg (25×10^6 tons) of the byproduct animal feed produced in 1980, or 70 percent of the total dried byproduct animal feed production.²

1.2.2 Grain Protein Feeds

Grain protein feeds, which include feeds produced at wet corn millers, distilled, rectified and blended liquors manufacturers, and malt beverages plants, represent the next largest category of animal feed production. This category accounts for 12.2 percent, or 3.9×10^6 Mg (4.3×10^6 tons) of dried byproduct animal feeds.^{3,4}

Wet corn milling accounts for 3.1×10^6 Mg (3.4×10^6 tons) or 80 percent, of the animal feed production in the grain protein feeds category. In this industry, corn is wet-milled to produce starch. The germ and gluten removed during the process are mixed with the bran, chaff, and steepwater concentrate and dried to produce gluten feed and gluten meal. Wheat and potato wet milling are also included in this category.

1.2.3 Animal Proteins

The animal protein category encompasses the animal and marine fats and oils industrial classification. Fish and feather meal production account for about 0.45×10^6 Mg (0.5×10^6 tons) of dried byproduct animal feed production, or approximately 1.5 percent of the total dried byproduct animal feed produced.⁵

Fish meal is produced at plants that process edible fish and at those that produce fish oil. At oil plants, fish are cooked and pressed to remove the oil, and the fish solids are dried for use as animal feed. In plants that process edible fish, the byproducts are dried to produce fish meal.

Feather meal is produced by hydrolyzing feathers in steam pressure cookers and then drying the resultant meal. Blood may or may not be added during processing to increase the protein content.

1.2.4 Other Feeds

The category "other" includes the remaining industries in the source category, which account for 15 percent of the total byproduct animal feed production. Dog, cat and other pet food (dried only) accounts for 2.4×10^6 Mg (2.6×10^6 ton), or 7 percent, of the total dried animal feed production.⁶ Grains, oilseed meals, and animal proteins are mixed, cooked, extruded as pellets, and dried in the production of dry animal feed in this industry.

Alfalfa dehydrators, the only segment of SIC 2048 that uses dryers in the production of animal feed, account for 1.1×10^6 Mg (1.2×10^6 tons) or 3.5 percent, of total dried animal feed production.³ Alfalfa is mowed in the field approximately four times during the growing season and is then dehydrated in a dryer prior to being pelletized and sold as an animal feed.

The beet sugar industry produces 1.3×10^6 Mg (1.4×10^6 tons) of dried beet pulp, which accounts for 4 percent of the total dried animal feed production.⁷ The beets are sliced and processed to remove the sugar, and the remaining beet pulp is then dried to produce animal feed.

1.3 INDUSTRY GROWTH AND EMISSIONS

As shown in Table 1-1, some growth in production capacity is forecast through 1985 for six of the eight industries in this source category. Wet corn milling is projected to have an annual growth rate of 7 percent through 1985, and it is estimated that in 1985 there will be the equivalent of 103 new/modified/reconstructed dryers with production of 2.2×10^6 Mg (2.6×10^6 tons) of animal feed per year. Four industry segments, soybean oil mills; dog, cat, and other pet food; distilled, rectified and blended liquors; and animal and marine fats and oils are projected to have annual growth rates of 5 percent through 1985. It is estimated that in 1985 there will be the equivalent of 56, 24, 16, and 20 new/modified/reconstructed dryers respectively in these industries, with production of 6.3×10^6 Mg (7.0×10^6 tons), 0.63×10^6 Mg (0.70×10^6 tons), 0.18×10^6 Mg (0.2×10^6 tons) and 0.22×10^6 Mg (0.24×10^6 tons) of animal feed per year. An annual growth rate of 2 percent is projected for alfalfa dehydrators in the period 1980 to 1985, and it is estimated that in 1985 there will be the equivalent of 22 new/modified/reconstructed dryers with production of 0.2×10^6 Mg (0.22 tons) of animal feed per year. No growth is projected for the remaining two industry segments through 1985. It is projected that the equivalent of 18 and 5 new/modified/reconstructed dryers will be needed in 1985 to maintain current production in these two industries. These dryers will account for 1.2×10^6 Mg (0.23×10^6 tons) and 0.05×10^6 Mg (0.06×10^6 tons) respectively of animal feed per year.

The primary emissions from animal feed dryers are particulate matter, and, in the case of direct-fired dryers, the products of combustion. Particulate matter emissions were the focus of this survey. In most cases, the particulate matter emissions represent valuable product (\$276 to \$386 per Mg, [\$250 to \$350 per ton]), and industry practice is to minimize product loss by using product recovery devices with the dryer.⁸ In addition to achieving product recovery, these devices also help the plants to meet State Implementation Plans (SIP). Where additional emission control is needed, mechanical collectors or wet centrifugal collectors are used. Wet collectors are generally the more efficient

control devices, but they also have potential for creating a wastewater disposal problem. Material collected by dry collectors can be recycled to the process; however, such recycling is generally not feasible with wet collection systems. In some instances, exhaust gas recycle systems are being used to conserve energy and reduce particulate matter emissions. No test data were found to evaluate the effectiveness of exhaust gas recycling.

Table 1-1 also contains estimates of annual emissions from new, modified or reconstructed facilities in 1985 for each industry segment. These estimates were developed to assess the magnitude of particulate matter emissions from animal feed dryers. Therefore, the estimates were calculated using the upper range of emission factors developed from test data and other information. These emission estimates show soybean oil mills have the greatest emissions of particulate matter in the source category; i.e., 4,763 Mg/yr (5,250 tons/yr) if all dryers are uncontrolled and 1,905 Mg/yr (1,905 tons/yr) if all dryers are equipped with pollution control equipment. Particulate matter emissions from the remaining industry segments of the source category are estimated to range from 1,140 Mg/yr (1,256 tons/yr) and 794 Mg (875 tons/yr) for uncontrolled and controlled wet corn milling to 65 Mg/yr (72 tons/yr) and 14 Mg/yr (15 tons/yr) for uncontrolled and controlled animal and marine fats and oils.

EPA Reference Method 5 (40 CFR 60, Appendix A [Revised July 1, 1979]) is the recommended procedure for measurement of the particulate matter content of animal feed dryer exhaust gases. Depending on the moisture content of the exhaust gas, the sample train may need to be modified to prevent blinding of the filter.

The SIP's for 47 States in which animal feed dryers are located require the control of particulate matter emissions. The SIP's are more stringent for new plants than for existing plants. New Jersey, Pennsylvania, and the South Coast Air Quality Management District have the lowest particulate matter emission limits; Arkansas, Illinois, and Indiana have developed particulate matter emission limits specific to animal feed drying plants.

2. INTRODUCTION

The Administrator of the U.S. Environmental Protection Agency is directed under Section 111 of the Clean Air Act to establish air pollution standards for new sources and in so doing has authority to:

1. Identify those categories of stationary emission sources that contribute significantly to air pollution and could be reasonably anticipated to endanger the public health and welfare;
2. Distinguish classes, types, and sizes within categories for the purpose of establishing standards; and
3. Establish standards of performance for stationary sources which reflect the emission reduction achievable through application of the best system of continuous emission reduction, taking into consideration the cost, energy, and environmental effects associated with the emission reduction.

The objective of this survey was to assess whether new source performance standards (NSPS) should be developed for dryers used in the production of animal feeds. Dryers covered by other new source performance standards (such as the grain dryers NSPS) were excluded from this study. The SIC codes and products which were examined during the survey are listed in Table 2-1. Information about processes, emissions, growth, and control equipment was gathered as follows:

1. Process and emission data were collected from literature searches, EPA regional offices, State and local air pollution control agencies, trade associations, equipment vendors, and plant visits.
2. Representatives of industry, government agencies, trade associations, and equipment vendors were contacted to obtain industry growth information. Additional information on growth was obtained from articles in trade journals and other publications.

TABLE 2-1. INDUSTRIES AND PRODUCTS

SIC code/industry classification	Primary products for use as animal feed
2046 Wet corn milling	Gluten feed, gluten meal
2047 Dog, cat, and other pet food	Dried pet food
2048 Prepared feeds and feed ingredients for animals and fowls, NEC	Alfalfa meal and pellets
2063 Beet sugar	Dried molasses beet pulp
2075 Soybean oil mills	Soybean cake and meal
2077 Animal and marine fats and oils	Fish meal, feather meal
2082 Malt beverages	Brewers dried spent grains
2085 Distilled, rectified and blended liquors	Distillers dried spent grains

3. Visits were made to the 11 plants listed in Table 2-2. An additional visit was made to an equipment manufacturer--Aeroglide Corporation, Raleigh, North Carolina.

Animal feed dryers are used to reduce the moisture content and sometimes to cool product prior to further processing, storage, and sale as an animal feed. Numerous types of dryers are available for drying animal feed ingredients: the direct-fired rotary, steam-tube rotary, tunnel or conveyor, flash, and ring dryers. The type of dryer used depends on the moisture content of the product entering the dryer and other factors, including the quantity of material to be processed, physical and chemical properties of the material to be dried, and site considerations.

In many instances, product recovery devices (i.e., primary cyclone collectors or discharge housings) are used with animal feed dryers. Therefore, unless otherwise noted, the pollution control equipment referred to in this report is any device used after a product recovery device to reduce particulate matter emissions. "Uncontrolled emissions" refers to the emissions measured after the product recovery device.

The industries that use animal feed dryers are described in subsequent sections of this report in terms of production capacity; projections of construction of new, reconstructed, and modified facilities; and production processes. Included are descriptions of emissions, emissions test data, emission control systems, State and local air pollution control regulations, and methods for emissions sampling and analysis.

3. SURVEY CONCLUSIONS

3.1 INDUSTRY GROWTH

Table 3-1 summarizes information on industry growth within the source category. These growth estimates were derived from straight line projections of historical production data and information obtained from industry contacts. The two largest industries, soybean oil mills and wet corn milling, are expected to grow at annual rates of 5 and 7 percent, respectively. An increase in the supply of soybeans or in the demand for soybean meal may cause this industry to grow at a slightly faster rate. Similarly, an increase in the demand for high fructose corn syrup (HFCS) by the soft drink industry or an increase in the production of alcohol from corn could cause the wet corn milling industry to grow at a faster rate.

The trend in alfalfa dryer replacements toward larger dryers may reduce the number of plants in operation by 1985. Dog, cat, and other pet foods; distilled liquor; and the animal and marine fats and oils industries are all expected to grow at 5 percent per year.

No growth is projected in the beet sugar and malt beverages industries. The number of plants in the beet sugar industry probably will decline from 1980 to 1985.

3.2 AVAILABILITY OF CONTROL TECHNOLOGY

Technology for the control of particulate matter emissions from animal feed dryers is readily available. The most common device associated with dryers is the cyclone, which is used to separate entrained product from the emission gas stream. In many cases, the cyclone collector is sufficient to control emissions to levels required by SIP's. Additional control can be achieved through the use of additional cyclones, multiclones,

TABLE 3-1. SOURCE CATEGORY GROWTH PROJECTIONS^a

Industry segment	Estimated annual growth, 1980-1985 percent	New/modified/reconstructed facilities, 1985

Animal and marine fats and oils	5	10	20	218	240

^aMRI estimate.

and other dry mechanical systems. With these secondary systems, emission control is the primary function, but product is also recovered. Better controlled dryers have some form of wet scrubber as the final control device. With direct-fired rotary dryers, "skimming" is widely practiced to return a portion of the emission gas stream to the dryer inlet. This recirculation reduces energy consumption and may reduce particulate matter emissions.

Technology for odor control is also available, and application was observed in two plant visits. One plant used packed-bed scrubbers with strong oxidants. The other plant used incineration as for odor control but retained a packed-bed scrubber as an alternative system.

3.3 SIGNIFICANT EMISSION SOURCES

An individual animal feed dryer with an associated product recovery device is the facility which would be affected by an NSPS for this source category. Maximum estimated uncontrolled emissions from an affected facility vary from about 20 to slightly less than 100 tons/yr. Therefore, this source category is not classified as a major source of emissions.

3.4 AVAILABILITY OF EMISSION DATA

The majority of the test data on animal feed dryers is from dryers used in gluten feed and meal, alfalfa meal, and beet sugar meal production. Eighty percent of the test data is for emissions after a product recovery cyclone. Insufficient data are available to correlate operational characteristics of the dryers or the physical properties of the product with emissions.

3.5 APPLICABLE METHODS FOR SAMPLING AND ANALYSIS

EPA Reference Method 5 is the procedure generally used for measuring particulate matter emissions in this source category. For the industry segments with high moisture content exhaust gases, some modifications to the Method 5 sample train will be required to prevent blinding of the sample filter.

In applying EPA Reference Method 5 the State of Iowa includes both the front and back half catches of the sampling train in determining the weight of particulate matter emissions. The emission limitations in Iowa

are adjusted to consider the contribution of the condensable particulate matter.

4. DESCRIPTION OF INDUSTRIES

This chapter describes the source category, animal feed dryers, and their applications. A generic description of dryers is presented in Section 4.1, and a discussion of the major industries which use animal feed dryers is presented in subsequent sections.

4.1 ANIMAL FEED DRYERS DESCRIPTION

Drying is the process of reducing the moisture content of a given material to the desired level by thermal means. The type of dryer which is used in an industry will depend on various factors including the following:¹

1. Physical properties of the feed material and dried product;
2. Drying characteristics of the product;
3. Specification of the dried product;
4. Estimated product losses both as dust and, where solvents are present, solvent losses;
5. Site considerations, including space and height available;
6. Energy availability; and
7. Emission regulations.

Dryers typically used in industrial drying operations may be classified as direct or indirect depending on the heating method. With direct-fired dryers, heated air and combustion gases flow through the dryer in direct-contact with the material being dried. Thus, emissions from direct fired dryers consist of the products of combustion as well as entrained particulate matter. With indirect dryers, heat is supplied indirectly by conduction. Examples of common indirect heating methods are steam tubes inside dryers, combustion gases heating the outside of dryers, and electrical heating elements. In indirect dryers, air flow through the

dryer is maintained to assist in the removal of water and other vapors. Emissions from indirect dryers consist of entrained particulate matter.

The most common types of dryers used in animal feed manufacturing are direct-fired rotary, steam-tube rotary, conveyor (tunnel), and pneumatic conveyor (i.e., ring and flash) dryers. In direct-fired rotary dryers, the material to be dried is fed into a rotating drum downstream from the introduction of combustion gases from the fire box and moves either concurrent or countercurrent to the flow of combustion gases. The material is tumbled in a rotating drum and may make a single or triple pass through the dryer.

In a steam-tube rotary dryer, the material is tumbled through a long rotating cylinder ringed with steam tubes. These dryers may be operated with natural or induced draft.

In conveyor or tunnel dryers, material is supported on a conveying screen that moves continuously. The conveyor may be single-pass or double-pass, depending on the tolerance of the material to the agitation. Heated air or hot gases (depending on whether a direct or indirect heat source is used) from below or above the conveyor pass through the material to effect drying.

In pneumatic conveyor dryers, moist product is dispersed into a heated gas stream. Moisture is removed as entrained product is carried upward in a conveying duct. The dried product is then separated from the gas stream by gravitational and centrifugal forces.

4.2 SOURCE CATEGORY

Dryers are used in the production of animal feeds in the following industries:

1. Soybean Oil Mills;
2. Wet Corn Milling;
3. Dog, Cat and Other Pet Foods;
4. Beet Sugar;
5. Alfalfa Dehydrators;
6. Animal and Marine Fats and Oils;
7. Distilled Liquor; and
8. Malt Beverages.

The following sections present discussions of these industries, their dryer applications, and emissions. Table 4-1 provides a list of individuals and firms that are knowledgeable in the source category and have been helpful in this study.

4.2.1 Soybean Oil Mills

4.2.1.1 Introduction. Soybean Oil Mills (SIC 2075) process soybeans to produce soybean oil and residual cake and meal that are dried and used as an animal feed. Currently, there are 121 oil mills operating in the U.S. with the capacity to produce 22.7×10^6 Mg/yr (25×10^6 tons/yr) of animal feed.^{2,3} Oil mills range in size from 544 to 6.8×10^5 Mg/yr (600 to 7.5×10^5 tons/yr) of animal feed. A typical new plant could be expected to produce 3.2×10^5 Mg/yr (3.5×10^5 tons/yr) of animal feed using three dryers.⁴ In 1977, 16.8×10^6 Mg (18.5×10^6 tons) of animal feed were produced with a value of \$3,735 million.² From 1972 to 1979 the production of animal feed grew at a 5 percent annual rate; this rate of growth is expected to continue through 1985.^{2,3}

Soybeans are grown over the same geographical range as corn. States with significant soybean acreage include Arkansas, Delaware, Illinois, Indiana, Iowa, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, North Carolina, Ohio, South Carolina, Virginia and Wisconsin. Presently soybean meal supplies most of the demand for high protein animal feed. Competition from gluten feed and meal and fish meal is important because of the substitutability of the products and the effects of marginal pricing on supply.

Appendix A, Table A-1, lists the companies which operate soybean oil mills.

4.2.1.2 Process Description. Oil is extracted from the beans by expeller or rotary screw pressing, batch-type hydraulic pressing, or solvent extraction. Each bushel (27.2 kg [60 lb]) of soybeans yields about 5 kg (11 lb) of oil and 21 kg (47 lb) of soybean meal with 0.9 kg (2 lb) normally lost in processing.⁵ Most U.S. soybeans are processed by the hexane extraction method in a continuous process. The subsequent discussion will pertain only to the solvent extraction process, since the mechanical extraction process produces soybean meal without the use of dryers.

Figure 4-1 presents a schematic of the overall features of a soybean processing plant using solvent extraction.

Soybeans are shipped to the processing facility by rail, truck, or barge. Upon arrival at the plant, the beans are cleaned and dried to between 10.5 and 11 percent moisture in grain dryers.

After the cleaning and drying steps, the beans are prepared for flaking. The beans are first passed through cracking mills or rolls where each bean is broken into four to eight parts. The hulls and meat are then separated in dehulling equipment, which may utilize a combination of screens, aspiration, and gravity tables. The hulls are collected by a product recovery cyclone and/or fabric filter and then sent through a grinding step prior to being conveyed to storage. The meat is transferred from the dehulling-separation equipment to the conditioning equipment. The conditioner is typically a steam-tube rotary unit that heats the meat to 71° to 77°C (160° to 170°F).

From the conditioning equipment, the meat is conveyed to the flaking rolls and then to the extractors. In the extractor, the flaked beans are contacted with hexane at approximately 52°C (125°F). The oil-hexane mixture (miscella) produced in the extractor flows to a working storage tank and then to hexane recovery operations. Hexane is removed from the miscella by steam distillation in a stripping column or still. The hexane vapor is condensed and returned to the solvent working tank after removal of water.

Spent flakes from the extractor are carried by closed screw or drag conveyor through a desolventizer. Four types of desolventizers are in use: (1) desolventizer-toaster system, (2) steam-jacketed conveyor, (3) flash desolventizer, and (4) vapor desolventizer-deodorizer system. Solvent vapors released in this operation are condensed and returned to the solvent working tank.

From a desolventizer-toaster system, the meal is dried first in a steam-tube rotary dryer and then is cooled before being sent to a grinder and storage for sale as animal feed.

4.2.1.3 Emissions. Soybean meal dryers are a source of particulate matter emissions at soybean oil mills. A typical large plant, of the

Figure 4-1. Soybean oil mill processing flow diagram.

type expected to be built to replace retired stock, will have two to three dryers, each capable of producing approximately 1.36×10^5 Mg/yr (1.5×10^5 tons/yr) of animal feed. Data received from the State of Illinois indicate uncontrolled emissions of 0.25 kg/Mg (0.5 lb/ton) were measured at one plant.⁶ Published emission factors show uncontrolled emissions from soybean meal dryers are 0.75 kg/Mg (1.5 lb/ton).⁷ It would be reasonable to conclude that on the average uncontrolled emission rates probably range from 0.25 kg/Mg to 0.75 kg/Mg (0.5 to 1.5 lb/kg). Using 0.25 kg/Mg (0.5 lb/ton), the estimated uncontrolled emissions from a new or replacement dryer would be 34 Mg/yr (38 tons/yr) of particulate matter. Using 0.75 kg/Mg (1.5 lb/ton), the uncontrolled emissions from a new or replacement dryer are estimated to be 84 Mg/yr (94 tons/yr) of particulate matter. The data received from the State of Illinois also show that controlled emissions range from 0.065 to 0.3 kg/Mg (0.13 to 0.6 lb/ton).⁶ Using 0.065 kg/Mg (0.13 lb/ton), the estimated controlled emissions from a new or replacement dryer would be about 9 Mg/yr (10 tons/yr) of particulate matter.

4.2.2 Wet Corn Milling

The Wet Corn Milling (SIC 2046) category includes primarily plants that manufacture corn or milo (soybean grain) by a wet milling process into starch, syrup, oil, sugar, and gluten feed and meal. Also included are plants that manufacture starch from other vegetable sources (wheat, potato, etc.) by a wet milling process.

Currently, there are 46 plants in this category in the U.S. with the capacity to produce 3.1×10^6 Mg/yr (3.4×10^6 tons/yr) of animal feed.^{8,9,10} Wet corn milling plants range in size from 5.4×10^4 to 2.9×10^5 Mg/yr (6×10^4 to 3.2×10^5 tons/yr) of animal feed. A typical new plant could be expected to produce 2.9×10^5 Mg/yr (3.2×10^5 tons/yr) of animal feed using eight dryers.⁴ In 1977, 2.4×10^6 Mg/yr (2.7×10^6 tons) of animal feed were produced with a value of \$352.9 million.⁸ From 1972 to 1979 the production of animal feed grew at a 7 percent annual rate; this rate of growth is expected to continue through 1985.^{8,9,10} The growth rate may increase to as much as 14 percent annually if demand increases for high fructose corn syrup (HFCS) or for commercially produced ethanol.¹²

Corn is grown principally in Illinois, Iowa, Indiana, Ohio, and Missouri. The majority of the wet corn milling operations are located in these States. With current milling practices each bushel of corn (25.4 kg [56 lb]) yields approximately 15 kg (34 lb) of starch, 5.9 kg (13 lb) of animal feed, and 0.9 kg (2 lb) of oil.^{13,14}

Table A-2 lists the companies which operate starch manufacturing plants.

4.2.2.2 Process Description. A process flow diagram for production of animal feed ingredients from wet corn milling is given in Figure 4-2. The major feed ingredients produced are gluten feed and gluten meal. Steepwater concentrate and germ meal (as indicated in Figure 4-2) are also produced.

Shelled corn is cleaned by sifters and an air stream. The cleaned kernels are then soaked (steeped) for 30 to 50 hours in a warm water solution which contains sulfur dioxide. Steeping removes some of the soluble material, toughens the center of the kernel (germ) and softens the protein rich material (gluten).

The softened kernels pass to degermination mills, which macerate the fiber and hull without crushing the germ. The macerated kernels are sent to separators to remove the germ. Germ is washed, dried, and sold or is internally processed into corn oil or germ meal.

The remaining portions of the corn (including starch fiber [bran] and gluten) are finely ground and then washed through screens to remove the fiber. The fiber is combined with steepwater concentrate and chaff and dried to produce gluten feed. Gluten feed contains approximately 10 percent moisture and consists of material with approximately 21 percent protein content. The final product may be pressed into pellets before it is sold.

The remaining aqueous suspension (millstarch) is processed in centrifugal separators to separate the lighter gluten from the heavier starch material. The gluten fraction is dried and sold as gluten meal for animal feed (containing approximately 60 percent protein). The starch is (1) washed, dried, and sold to the food, paper, and textile industries; (2) further processed to modified starch products or dextrin; or (3) converted to syrup or sugar.

Figure 4-2. Wet corn milling flow diagram.

4.2.2.3 Emissions. Animal feed dryers are a source of particulate matter emissions at wet corn mills.¹⁵ A typical large plant, of the type expected to be built to replace retired stock will have four to eight dryers, each capable of producing 3.6×10^4 Mg/yr (4.0×10^4 tons/yr) of animal feed. Test data indicate uncontrolled emissions for each dryer may range from 0.1 to 0.5 kg/Mg (0.2 to 1.0 lb/ton).^{16,17} Using 0.5 kg/Mg (1.0 lb/ton), the estimated uncontrolled emissions from a new or replacement dryer would be 18 Mg/yr (20 tons/yr) of particulate matter. Available data suggest that controlled emissions may range from 0.15 kg/Mg to 0.35 Kg/Mg (0.3 to 0.7 lb/ton).^{17,18} Using 0.15 kg/Mg (0.3 lb/ton), estimated controlled emissions from a new or replacement dryer would be 5.4 Mg/yr (6 tons/yr) of particulate matter.

4.2.3 Dog, Cat, and Other Pet Food

4.2.3.1 Introduction. Dog, Cat, and Other Pet Food (SIC 2047) manufacturers process cereal, meat products, and other ingredients into canned, frozen, or dry animal feeds. Only dry food manufacturing involves the use of dryers and is included in this survey.

Currently, there are 272 plants operating in the U.S. that produce both "wet" and dry foods.⁹ Current dry food production is 2.4×10^6 Mg/yr (2.6×10^6 tons/yr) accounting for 58 percent of the feed produced in this industry.¹⁹ Pet food plants range in size from 4.5×10^4 to 9.1×10^4 Mg/yr (5.0×10^4 to 1.0×10^5 tons/yr). A typical new plant could be expected to produce 9.1×10^5 Mg/yr (1×10^5 tons/yr) using three dryers.⁴ In 1977, 1.9×10^6 Mg (2.1×10^6 tons) of dry pet food were produced with a value of \$1,208 million.⁸ From 1972 to 1979, the production of dry pet food grew at a 3 to 5 percent annual rate; a 5 percent rate of growth is expected to continue through 1985.^{8,19}

Table A-3 lists the companies which operate dry pet food plants.

4.2.3.2 Process Description. Figure 4-3 gives a representative process flow diagram of a dry pet food manufacturing process. Dried pet food is formulated from grains, soybeans, meat and meat by-products, tallow, vitamins, minerals, and other by-product meals. The typical production process consists of grinding and mixing, expanding in a cooker, pellet extruding, cooling, drying and cooling, and packaging. Grains and beans received in bulk (already dried to meet a moisture

(*) Particulate and vaporous emissions

Figure 4-3. Dry pet food manufacturing flow diagram.

specification) are stored in silos and then ground to desired particle size in hammermills. Vacuum collection systems are installed at transfer points in the process to reduce fugitive dust, recover product, and maintain cleanliness.

The expander/cooker-extruder-cooler unit produces pet food pellets with approximately 12 percent moisture content. These pellets are evenly distributed on the dryer oven conveyor where they make one or more passes before emerging cooled and dried to about 8 to 10 percent moisture content. Typical of dryers used in the industry is the tunnel dryer with either one or two passes that is sold in sizes ranging from 2.27×10^3 to 2.27×10^4 kg/h (4×10^3 to 4×10^4 lb/h). The heat source may be natural gas or oil burners, steam coils, electrical resistance elements, or waste heat. To increase the evaporation rate, dryers are equipped with blowers to provide controlled circulation. An air flow of about $9.4 \text{ m}^3/\text{s}$ (20,000 acfm) is typical for a dryer of 9 Mg/h (10 tons/h) capacity. Dryers are equipped with cyclone collectors for product recovery.

4.2.3.3 Emissions. Pet food dryers are a source of particulate matter emissions at pet food manufacturing plants. A typical plant, of the type expected to be built to replace retired stock, will have two to three dryers, each capable of producing 4.5×10^4 Mg/yr (5×10^4 tons/yr) of animal feed. Uncontrolled emissions of 0.8 kg/Mg (1.6 lb/ton) have been estimated from a manufacturers test of a representative system.²⁰ Using this figure, the estimated uncontrolled emissions from a new or replacement dryer would be 36 Mg/yr (40 tons/yr) of particulate matter. According to manufacturer's test data, controlled emissions are 0.005 kg/Mg (0.01 lb/ton).²¹ Using this figure, the estimated controlled emissions from a new or replacement dryer would be 0.23 Mg/yr (0.25 tons/yr) of particulate matter.

4.2.4 Beet Sugar

4.2.4.1 Introduction. Beet Sugar (SIC 2075) plants process beets to produce sugar; the residual beet pulp is dried and sold as an animal feed. Currently, there are 57 beet sugar plants operating in the U.S. with the capacity to produce 1.3×10^6 Mg/yr (1.4×10^6 tons/yr) of animal feeds.^{22,23} Beet sugar plants range in size from 9×10^3 to

4.5×10^4 Mg/yr (1×10^4 to 5×10^4 tons/yr). A typical plant could be expected to produce 2.4×10^4 Mg/yr (2.6×10^4 tons/yr) of animal feed using two dryers.⁴ In 1977, 1.27×10^6 Mg (1.4×10^6 tons) of animal feed were produced with a value of \$106.9 million.²² From 1972 to 1979 the production of animal feed remained essentially unchanged, varying plus or minus 1 percent annually.²² No growth is projected through 1985, and negative growth is possible. The manufacture of beet sugar is a seasonal operation. In most of the U.S. the harvest period lasts from October until the end of November, by which time the harvest must be completed to avoid freezing of the beets in the ground. It is customary to build storage piles of beets and to continue factory operations for about two more months, resulting in an operating season of approximately 120 days. Table A-4 lists the companies which operate beet sugar plants.

4.2.4.2 Process Description. A representative flow diagram of a beet sugar processing operation is presented in Figure 4-4. Beets are weighed at the receiving station and undergo an initial cleaning that removes most of the dirt, rocks, and other debris. From here the beets are moved in water flumes to supply hoppers located over the beet slicing mechanism. Horizontal axis, rotating drum slicers are used to slice the beets into pieces 2 to 3 millimeters (mm) (0.08 to 0.12 in.) thick and up to 15 centimeters (cm) (5.9 in.) long. Next, the sugar is extracted from the beet slices in a diffuser. In a typical diffuser, the sliced beets travel up a covered sloping trough countercurrent to a stream of hot water. The raw diffusion juice leaving the lower end of the diffuser is screened to remove small pieces of sugar beet. The pulp leaves the diffuser with a water content of about 95 percent and is pressed in screw-type presses until it contains approximately 75 to 80 percent moisture. The water pressed out of the pulp contains some sucrose and is returned to the diffuser. The pressed pulp is enriched by the addition of molasses. This enriched pulp is dried in direct-fired rotary dryers (fired by natural gas, fuel oil, lignite or coal) to a final moisture content of 6 to 10 percent and is cooled and stored for sale as animal feed. At the discharge end of the dryer drum, the product enters a large discharge housing, causing it to drop out of the gas stream into a scroll. Hot gases rise to the top of the enlarged housing and pass

Figure 4-4. Beet sugar processing flow diagram.

through an induced draft fan to a cyclone for the control of particulate matter.

4.2.4.3 Emissions. Beet pulp dryers are a source of particulate matter emissions at beet sugar plants. A typical plant, of the type expected to be built to replace retired stock, will have two dryers, each capable of producing approximately 1.63×10^4 Mg/yr (1.8×10^4 tons/yr) of animal feed. Test data indicate uncontrolled emissions range from 0.75 to 3.0 kg/Mg (1.5 to 6.0 lb/ton).^{24,25} Using 3.0 kg/Mg (6.0 lb/ton), the estimated uncontrolled emissions from a new or replacement dryer would be 49 Mg/yr (54 tons/yr) of particulate matter. Controlled emissions have been reported to range from 0.15 to 0.75 kg/Mg (0.3 to 1.5 lb/ton).^{24,26} Using 0.15 kg/Mg (0.3 lb/ton) and 0.75 kg/Mg (1.5 lb/ton), the estimated controlled emissions from a new or replacement dryer would be 2.4 Mg/yr (2.7 tons/yr) and 12 Mg/yr (13.5 tons/yr), respectively.

4.2.5 Alfalfa Dehydrators

4.2.5.1 Introduction. Alfalfa Dehydrators (SIC 2048) dry "green" or "sun-cured" alfalfa for use as an animal feed. Currently, there are 180 alfalfa dehydrating plants operating in the U.S. with the capacity to produce 1.1×10^6 Mg/yr (1.2×10^6 tons/yr) of animal feed.^{8,27} Alfalfa dehydrators range in size from 900 to 3.18×10^4 Mg/yr (1×10^3 to 3.5×10^4 tons/yr). A typical new plant could be expected to produce 1.9×10^4 Mg/yr (2.1×10^4 tons/yr) of alfalfa using two dryers.⁴ In 1977, 1.1×10^6 Mg/yr (1.2×10^6 tons) of animal feed were produced with a value of \$91 million.⁸ From 1972 to 1979, the production of alfalfa has remained essentially stable.^{8,9} A 2 percent rate of growth is expected through 1985.²⁸

Alfalfa dehydrators are located throughout the country except in New England and the southeastern States. The center of the industry is in the Northern Plains States. Alfalfa dehydrators are typically located within 16 kilometers (10 miles) of the source of alfalfa. Table A-5 provides a list of alfalfa dehydrating plants.

4.2.5.2 Process Description. A representative flow diagram of an alfalfa dehydration plant is shown in Figure 4-5. Chopped alfalfa ("chops") is received at the plant and dried to 8 to 10 percent moisture content, usually in a direct-fired rotary drum dryer. Alfalfa dryers typically

(*) Particulate and vaporous emissions

Figure 4-5. Alfalfa pellet production flow diagram.

operate in the range of 982° to 1093°C (1800° to 2000°F). The temperature of exhaust gases from the dryer ranges from 121° to 160°C (250° to 320°F). Customarily, a cyclone is used to separate the product from the gases as they leave the dryer. The primary function of this cyclone is product recovery. The product recovered in the cyclone enters the hammermill, which reduces the dehydrated chops to meal. The meal then enters a negative pneumatic conveyor, which discharges into the meal collection bin. From the meal bin, the product may go to bagging, bulk storage, or pelletizing operations. Additional cyclone collectors are used to recover product and to reduce emissions from the hammermill, pellet mill, and associated collecting bins. The air streams from these secondary cyclones are usually ducted back to the primary cyclone collector.

4.2.5.3 Emissions. The dryers, hammermills, and pellet mills are sources of emissions at alfalfa dehydrating plants. A typical large plant, of the type expected to be built to replace retired stock, will have two dryers, each capable of producing approximately 9×10^3 Mg/yr (1×10^4 tons/yr). Test data indicate uncontrolled emissions range from 0.75 to 5.0 kg/Mg (1.5 to 10.0 lb/ton).^{29,30} Using 5.0 kg/Mg (10.0 lb/ton), uncontrolled emissions from a new or replacement dryer would be 45 Mg/yr (50 tons/yr) of particulate matter. Controlled emissions range from 0.5 to 1.5 kg/Mg (1.0 to 3.0 lb/ton).²⁹ Using 0.5 kg/Mg (1.0 lb/ton), controlled emissions from a new or replacement dryer would be 4.5 Mg/yr (5 tons/yr) of particulate matter.

4.2.6 Animal and Marine Fats and Oil

4.2.6.1 Introduction. Animal and Marine Fats and Oils (SIC 2077) include plants that produce fish meal and feather meal, which are dried and used as animal feed. Currently, there are 67 companies that produce fish and feather meal in the U.S. with the capacity to produce 5.1×10^5 Mg/yr (5.6×10^5 tons/yr).^{31,32} Fish and feather meal plants range in size from 7.3×10^3 to 1.27×10^4 Mg/yr (8×10^3 to 1.4×10^4 tons/yr) and 4.5×10^3 to 4.35×10^4 Mg/yr (5×10^3 to 4.8×10^4 tons/yr), respectively. A typical new fish meal plant could be expected to produce 1.63×10^4 Mg/yr (1.8×10^4 tons/yr) of animal feed using two to three dryers, while a

typical new feather meal plant could be expected to produce 1.36×10^4 Mg/yr (1.5×10^4 tons/yr) using two dryers.⁴ In 1977, 2.56×10^5 Mg/yr (2.82×10^5 tons) of fish meal and 1.58×10^5 Mg/yr (1.74×10^5 tons) of feather meal were produced, with values of \$82 and \$39 million, respectively.^{31,32} From 1972 to 1979, the production of fish meal grew at a 4 percent annual rate while the production of feather meal grew at a 3 percent annual rate.³² Through 1985, fish meal production is expected to remain essentially stable while feather meal production is expected to grow at a 5 percent annual rate.^{34,35}

Table A-6 lists the companies that operate fish meal and feather meal plants.

4.2.6.2.1 Process description--fish meal. A representative process flow diagram of a fish meal plant is given in Figure 4-6. Fish are pumped from boats into a measuring device, which is calibrated into a measure known as "one-thousand fish." One-thousand fish is equivalent to approximately 0.36 m^3 ($22,000 \text{ in.}^3$) or 302 kg (665 lb). From here the fish are moved to a raw storage bin. Fish are moved from the raw storage bin via a screw conveyor into a live steam cooker. The cooker is a long horizontal section of the screw conveyor fitted with a cover. Cooking breaks the oil sacs and disintegrates the fish. From the live steam cooker the mixture is conveyed to dewatering presses, which reduce the fish meal to 42 to 50 percent moisture content. The water and oil pressed from the fish are processed through shaker screens to remove residual solids and are then centrifuged to separate the oil from water and fish solubles. The fish oil recovered is a final product. The water generated from the above process is known as "stick water" and is sent to an evaporator to concentrate the soluble and suspended solids. These fish solubles are added to the meal to produce a higher quality fish meal known as whole fish meal. From the dewatering presses, the fish meal enters rotary drum dryers where it is dried to approximately 10 percent moisture. The meal is recovered by product recovery cyclones on the end of the dryer and then conveyed to bulk storage. The exhaust gases are passed through an odor scrubber and then exhausted to the atmosphere.

Figure 4-6. Fish meal production flow diagram.

4.2.6.2. Process description--feather meal. Feathers are received from chicken or turkey processing plants and are hydrolyzed to a meal in continuous or batch live steam or steam-tube pressure cookers. Blood may be added to the feathers before or after hydrolyzation.

The moisture content of the feather meal is reduced from approximately 70 percent to 7 percent in steam-tube rotary dryers. The feather meal then goes through a cooling and moisture adjustment process where dry or wet feather meal is added to the product as needed to adjust the final moisture content to 10 percent.

Exhaust gases from the pressure cookers, dryers, and coolers are collected and routed through cyclone collectors to remove suspended particulate matter and then are shunted to an odor control system. Feather meal is recovered from the cyclones and is returned to the process. A representative flow diagram of a feather meal plant is presented in Figure 4-7.

4.2.6.3 Emissions. The fish and feather meal dryers are sources of particulate matter emissions in these industries. A typical plant, of the type expected to be built to replace retired stock in the fish meal industry, will have two to three dryers, each capable of producing approximately 7.3×10^3 Mg/yr (8×10^3 tons/yr). No test data are available for either controlled or uncontrolled emissions from fish meal dryers. Using the factor of 0.005 kg/Mg (0.1 lb/ton) of uncontrolled emissions given in AP-42, a new or replacement dryer would be expected to emit less than 0.9 Mg/yr (1 ton/yr) of particulate matter.³⁶

A typical plant, of the type expected to be built to replace retired stock in the feather meal industry, will have two to four dryers, each capable of producing approximately 1.45×10^4 Mg/yr (1.6×10^4 tons/yr). Test data indicate uncontrolled emissions of 0.3 kg/Mg (0.6 lb/ton).³⁷ Using 0.3 kg/Mg (0.6 lb/ton), the estimated uncontrolled emissions from a new or replacement dryer would be 4.4 Mg/yr (4.8 tons/yr) of particulate matter per dryer. No data are available to estimate controlled emission rates.

4.2.7 Distilled Liquor

4.2.7.1 Introduction. Distilled Liquors (SIC 2085) include plants that manufacture alcoholic liquor by distillation and rectification and

(*) Particulate and vaporous emissions

Figure 4-7. Feather meal production flow diagram.

that produce distillers' dried grain for sale as an animal feed. Currently, there are 93 distillers operating in the U.S. (not all of these produce dried grains) with the capacity to produce 4.45×10^5 Mg/yr (4.9×10^5 ton/yr) of animal feed.^{38,39} A typical new plant could be expected to produce 2.27×10^4 Mg/yr (2.5×10^4 tons/yr) of dried grain using two dryers.⁴ In 1977, 3.5×10^5 Mg/yr (3.87×10^5 tons) of dried grain were produced with a value of \$42 million.⁴⁰ From 1972 to 1979, the production of animal feed grew at a 3 percent annual rate; a 5 percent annual rate of growth is expected through 1985.^{40,41}

Table A-7 lists the companies which operate distilleries.

4.2.7.2 Process Description. Figure 4-8 shows a general process flow diagram of a distilled spirits plant. Cereal grains are ground, cooked to gelatinize the starch, cooled, and saccharified with malt. After settling for a period to permit saccharification, the mash is cooled to fermentation temperature, inoculated with yeast, and allowed to ferment from 3 to 5 days. The fermented mash is distilled, and the whole spent stillage is further processed to make distillers' dried grains.

First, the whole stillage is separated over screens with the coarse fraction being retained on the screens and the suspended solids and liquids passing through the screens. The coarse fraction is generally pressed for further removal of water before drying, and the liquids and suspended solids may be either centrifuged to remove suspended solids or evaporated to a syrup (30 to 40 percent solids).

In the production of distillers' dried grains with solubles, the screened and pressed fraction and syrup are mixed and dried, generally in steam-tube rotary dryers. In the production of distillers dried grains, only the coarse fraction is dried.

4.2.7.3. Emissions. Spent grain dryers are a source of particulate matter emissions at distilleries. A typical plant, of the type expected to be built to replace retired stock, will have two dryers, each capable of producing 1.36×10^4 Mg/yr (1.5×10^4 tons/yr) of dried grains. No test data were available for uncontrolled or controlled emissions. An emission factor of 2.5 kg/Mg (5.0 lb/ton) is given in AP-42 for uncontrolled

(*) Particulate and vaporous emissions

Figure 4-8. Distilled spirits production flow diagram.

emissions.⁴² Using 2.5 kg/Mg (5.0 lb/ton), the expected uncontrolled emissions from a new or replacement dryer would be 34 Mg/yr (37.5 tons/yr).

4.2.8 Malt Beverages

4.2.8.1 Introduction. Malt Beverages (SIC 2082) plants process cereal grains into malt beverages and dry the spent grain for use as an animal feed. Currently, there are 88 plants operating in the U.S. (not all produce brewers' dried grains) with the capacity to produce 3.63×10^5 Mg/yr (4×10^5 tons/yr) of animal feed.^{43,44} Breweries range in size from 1.8×10^3 to 1.8×10^4 Mg/yr (2×10^3 to 2×10^4 tons/yr) of brewers' dried grains. A typical new plant could be expected to produce 1.8×10^4 Mg/yr (2×10^4 tons/yr) of brewer's dried grain using two dryers.⁴ In 1977, 3.54×10^5 Mg (3.9×10^5 tons) of animal feed were produced with a value of \$46 million.^{40,44} From 1972 to 1979, the production of brewers' dried grain remained essentially stable; this stable level of production is expected to continue through 1985.^{40,45}

At one time, general industry practice was to sell wet spent grains for feed or to bury or to flush the material into nearby streams. Many brewers still sell wet grains for feed. Table A-8 lists the companies which operate malt beverage plants.

4.2.8.2. Process Description. A representative process flow diagram of a malt beverage plant is given in Figure 4-9. The first step in the production of brewers' dried grains process is to move the spent grain from the spent grains holding hopper to the dewatering press surge hopper and then by screw conveyor to the rotary dewatering press. Three lines of materials leave the press: the water produced is sent to an effluent centrifuge, most of the pressed grain is sent to dryers, and the remaining portion of the pressed grain leaves along another conveyor to the wet spent grains storage bin. Some of the wet grains, along with some of the material from the effluent centrifuge, are mixed back into the dried grain to produce the raw feed material.

4.2.8.3. Emissions. Spent grain dryers are a source of particulate matter emissions at breweries. A typical large plant, of the type expected to be built to replace retired stock, will have two dryers, each capable of producing 1.1×10^4 Mg/yr (1.2×10^4 tons/yr). No test data are available for uncontrolled emissions. AP-42 lists an uncontrolled

(*) Particulate and vaporous emissions

Figure 4-9. Malt beverage production flow diagram.

emission factor of 2.5 kg/Mg (5.0 lb/ton).⁴² Using 2.5 kg/Mg (5.0 lb/ton), the estimated uncontrolled emissions from a new or replacement dryer would be 27 Mg/yr (30 tons/yr) of particulate matter. Controlled emissions have been reported to be approximately 1.0 kg/Mg (2.0 lb/ton).⁴⁶ Using 1.0 kg/Mg (2.0 lb/ton), the estimated controlled emissions from a new or replacement dryer would be 11 Mg/yr (12 tons/yr) of particulate matter.

5. AIR EMISSIONS DEVELOPED IN SOURCE CATEGORY

5.1 PLANT AND PROCESS EMISSIONS

The principal air pollutant resulting from the drying of products used as animal feeds is particulate matter. Sulfur dioxide (SO_2), hexane, and odor emissions may also occur. In direct-fired dryers, the products of combustion are present in the emissions. Direct-fired, rotary drum dryers use natural gas, fuel oil, coal, or lignite as a fuel source. If fuels other than natural gas are used, SO_2 may be emitted. Furthermore, at soybean oil mills hexane may be emitted from the animal feed dryers. No data were found to quantify the presence of SO_2 and hexane emissions from dryers. Table 5-1 is a summary of particulate matter emission factors from typical dryers, which was developed from available test and permit data.

5.2 TOTAL NATIONAL EMISSIONS FROM SOURCE CATEGORY

Animal feed drying produces primarily particulate matter emissions but may also produce sulfur dioxide, odor, and other trace substances (i.e., hexane). Estimates of current national particulate matter emissions are given in Table 5-2. The annual production figures given in Table 5-2 were obtained from published U.S. Department of Commerce statistics for 1975 through 1979 and from projected or estimated statistics for 1980.¹⁻¹⁰ The uncontrolled emission factors given in Table 5-2 are the upper limit of the range of the emission factors given in Table 5-1 or are published emission factors.^{11,12} Consequently, the emissions given in Table 5-2 are thought to represent maximum estimated emissions for each industry. The largest source of particulate matter emissions is the soybean oil mill segment, which emits an estimated 17,010 Mg/yr (18,750 tons/yr). The

^aAnnual production estimated from References 1-10.^bExpressed in terms of Mg and tons of dried product.^cFactor given in Reference 11.^dCalculated from available emission test data.^eEstimated from equipment manufacturer's test data.^fAssumed to be the same as for spent grain dryers in the malt beverages industry due to similarity of processes.^gFactor given in Reference 12.

smallest source of particulate matter is the animal and marine oils and fats segment, which emits an estimated 152 Mg/yr (168 tons/yr).

There is potential for sulfur dioxide emissions when direct-fired dryers are used with oil, coal, or lignite as fuel. However, natural gas is presently the fuel most frequently used. There are little or no data available upon which to base estimates of sulfur dioxide emissions from this source category.

6. EMISSION CONTROL SYSTEMS

6.1 CONTROL APPROACHES

Particulate matter control devices used at plants in the source category include: cyclones used singly, in series, and in parallel; venturi scrubbers; orifice-type scrubbers; mechanical centrifugal collectors with water spray; and wet mechanical scrubbers. Packed bed scrubbers and incinerators are used for odor control on the emissions from the drying of feather meal and fish meal.

Recently, several dryer manufacturers have begun to include partial exhaust gas recirculation as a part of the dryer system. Recirculation of the hot gases reduces the energy requirements of the dryer and is claimed to reduce emissions.

6.1.1 Product Recovery for the Animal Feed Dryer

Efficient product recovery is essential to profitable plant operations, and product recovery devices are usually purchased as part of a drying system. These devices separate the exhaust gases from the entrained product. Large discharge housings at the end of the dryer drum and cyclones are among the devices used for product recovery. Discharge housings or settling chambers allow the product to drop out of the exhaust gas stream, and cyclones separate particulate matter from the effluent gas by changing the direction and velocity of the stream.

6.1.2 Emission Control for the Animal Feed Dryer

Table 6-1 lists types of control devices used in the industries which make up the animal feed source category. This table was compiled using information obtained in plant visits and from emission test reports, industry contacts, and manufacturers' literature.

6.1.2.1 Dry Collectors. A cyclone with a high inlet velocity, small diameter, and long cone is commonly called a high-efficiency

TABLE 6-1. CONTROL DEVICES USED ON EMISSIONS FROM
ANIMAL FEED DRYERS BY SIC CODE

SIC Code	Industry type	Control device
2046	Wet corn milling	High efficiency cyclones Multiclones, Venturi scrubbers
2047	Dog, cat and other pet foods	Multiclone
2048	Prepared feeds, NEC	Wet scrubbers, Partial recycle of exhaust air
2063	Beet sugar	Cyclones, Partial recycle of exhaust air
2075	Soybean oil mills	High efficiency cyclones
2077	Animal and marine fats fats and oils	Incinerators, Packed bed scrubbers
2082	Malt beverage	Mechanical, centrifugal collectors with water spray
2085	Distilled liquor	Mechanical, centrifugal collectors with water spray

cyclone. One type of high-efficiency cyclone consists of a cylinder with a tangential gas inlet, an axial gas outlet, and a conical lower section with an axial dust outlet. The tangential, high-velocity gas entry imparts a circular motion to the gas stream; the particles, because of their greater inertia, tend to concentrate on the wall of the cyclone. The gas follows a double vortex path, spiraling down at the outside and up at the inside to the gas outlet. The downward spiral assisted by gravity carries the particles to the dust outlet.

Cyclone efficiency increases with an increase in any of the following: density of the particulate matter, particle diameter, inlet velocity, length of cyclone, ratio of cyclone body diameter to cyclone outlet diameter, and number of gas revolutions within the cyclone.¹

6.1.2.2 Wet Collectors. A variety of wet collection devices exist for the control of particulate matter emissions. These are described below.

In a mechanical, centrifugal collector with water sprays, a spray of water is added to the inlet to increase collection efficiency. The wet fan serves as a surface for impingement of dust particles. The spray formed by the fan functions mainly to keep the blades wet and flush away the collected dust. This type of collector has limited effectiveness for particulate matter in the submicron range and is subject to dust buildup and corrosion at the blades.²

In a venturi scrubber, the exhaust gas passes through a venturi to which water is added at the throat. Venturi scrubbers commonly have gas velocities at the throat that range from 4,570 to 6,100 meters per minute (mpm) (15,000 to 20,000 feet per minute [fpm]).³ Pressure drops range from 2,488 to 7,565 pascals (Pa) (10 to 30 inches H₂O).³ Impaction of the particles by liquid drops is the predominate collection mechanism. The high velocity at the throat causes turbulence, which promotes intimate particle/liquid contact. The wetted particles and droplets are collected in a cyclone spray separator. A venturi scrubber can have a high (98+ percent) collection efficiency for particulate matter in the submicrometer range, if operated at a high pressure drop. These scrubbers are not used commonly by industries in the animal feed source category.

In orifice type scrubbers, the gas stream passes over a reservoir of scrubbing liquid at high velocity just before entering an orifice. The high velocity of the gas entrains the scrubbing liquid droplets, which interact with the particulate matter in and immediately after the orifice. Centrifugal forces, impingement, and turbulence cause wetting of the particles and their collection. Zig-zag or baffle plates remove spray droplets at the gas exit.

In wet mechanical scrubbers, the spray of scrubbing liquid is generated by a mechanical rotor or fan which disperses the scrubbing liquid into droplets. The most efficient wet mechanical systems are designed to produce finely divided liquid droplets and extreme turbulence, which increases chances of collision between dust particles and liquid droplets to increase capture efficiency.⁴ Like mechanical centrifugal collectors with water sprays, these scrubbers are subject to particulate matter buildup or corrosion at the rotor blades.

6.1.2.3 Odor Control. Packed bed scrubbers used for odor control also remove particulate matter. Odor removal by wet scrubbing is a function of the residence time of the odor-laden air in the scrubber, the available contact area, and the solubility of the odor-causing pollutant in the scrubbing liquid. Packed bed scrubbers observed in the control of animal feed dryers typically contain three sections. In the first section, water sprays are used to cool the exhaust gases and to entrain and remove some of the odor-causing pollutant. The second chamber contains a packed bed to increase retention time and contact area. Sulfuric acid (5 to 10 percent) is sprayed into this chamber to oxidize the odor-causing particles to nonodorous or easily removable compounds. Next, the gas stream is contacted with chlorine gas to further oxidize the odor-causing pollutant. In the third chamber, caustic is sprayed onto a packed bed to neutralize the scrubbing solution prior to discharge.

Water and chemical flow rates in packed bed scrubbers vary depending on the exhaust gas flow rate. An observed packed bed scrubber controlling a fish meal dryer had a gas flow rate of $17.7 \text{ m}^3/\text{s}$ (37,500 cfm), a water flow rate of $0.063 \text{ m}^3/\text{s}$ (1,000 gpm), and sulfuric acid and caustic flow

rates each of 0.02 m³/s (384 gpm).⁴ The collection efficiency for this scrubber is claimed to be 98 percent of all particles larger than 8 µm.⁵

Incinerators and waste heat boilers have been used to control odors from fish and feather meal dryers. The use of the exhaust gas from the product recovery cyclone as combustion air for the burner in the plant boiler is also used as an odor control system in these industries.

6.2 BEST SYSTEMS OF EMISSION REDUCTION

The available data are too limited to determine the most effective systems of emission control for each industry in the source category. However, the available information does indicate that the most effective system of control would include the use of pollution control devices in series with product recovery devices. Energy conservation programs have led some industries to employ exhaust gas recirculation with claims of both energy savings and emissions reduction.

7. EMISSION DATA

7.1 AVAILABILITY OF DATA

Emission test data were obtained from State and local control agencies, plants, and equipment vendors. Particulate matter sampling was typically conducted using EPA Reference Method 5 (with modification as required by the situation). In one case, a high-volume sampling train was used. Odor sampling was conducted at one plant using ASTM Method D 1391-57.

Table 7-1 includes (1) results of particulate matter emission testing and (2) calculated allowable emissions using the appropriate State regulation (typically in the form of a process weight rate equation). The emissions presented in the table are characterized as controlled or uncontrolled depending on whether or not the device associated with the dryer was used primarily for product recovery. In only a few cases were test data obtained for controlled emissions.

Insufficient data were available on dryer operating conditions and characteristics of the feed material to determine the effect, if any, of these factors on particulate matter emissions.

7.2 SAMPLE COLLECTION AND ANALYSIS

EPA Reference Method 5 is the recommended method for measuring particulate matter emissions in this source category. Depending upon the moisture content of the exhaust gas, modification of the method may be required.

8. STATE AND LOCAL EMISSIONS REGULATIONS

This chapter provides information on State and local regulations that are applicable to animal feed dryers. These data were compiled from telephone contacts with State and local pollution control agencies and from the Environment Reporter.^{1,2}

8.1 SUMMARY OF EMISSION REGULATIONS

Animal feed drying plants operate in 47 States. All 47 States regulate particulate matter emissions from new and existing plants. The State regulations for new plants (see Table 8-1 following page 8-2) are more stringent than those for existing plants. All but four States have opacity limitations (Table 8-1). Most of the States limit opacity to 20 percent with exceptions that permit higher levels for a small percentage of time in an hour or a day. In addition, most States have odor restrictions on animal feed dryers restricting odors to no more than 150 odor concentration units as determined by an odor panel.

Thirty-four of the forty-seven States use the process weight rate equations shown below to determine allowable particulate matter emissions from animal feed dryers.

$$\text{Equation Set 1: } E = 3.59 P^{0.62} \quad P \leq 30 \text{ tons/h}$$

$$E = 17.31 P^{0.16} \quad P > 30 \text{ tons/h}$$

$$\text{Equation Set 2: } E = 4.10 P^{0.67} \quad P \leq 30 \text{ tons/h}$$

$$E = 55 P^{0.11-40} \quad P > 30 \text{ tons/h}$$

where E equals allowable particulate matter emission rate in pounds per hour and P equals process weight rate in tons per hour. Twenty-two States use Equation Set 2, ten States use Equation Set 1, and two States use both equations for different conditions. Using Equation Set 1 and assuming process weight rates of 18 and 36 Mg/h (20 and 40 tons/h),

allowable emissions would be 10.4 kg/h (23.0 lb/h) and 14.2 kg/h (31.2 lb/h), respectively. Using Equation Set 2 and the same process weight rate assumptions, allowable emissions would be 13.8 kg/h and 19.3 kg/h (30.5 lb/h and 42.5 lb/h), respectively.

New Jersey, Pennsylvania, and the South Coast Air Quality Management District have the lowest particulate matter emission limits. A dryer processing 4.5 Mg/h (5 tons/h) would be restricted to 3.9 kg/h (8.5 lb/h) of particulate matter emissions in these three areas but would be allowed to emit 5.4 kg/h (12 lb/h) of particulate matter (based on Equation Set 2) in most of the remaining States.

Three States--Arkansas, Illinois, and Indiana--have particulate matter emission limits specific to animal feed drying plants. Arkansas has a specific regulation for poultry feed mills and soybean oil mills (Table 8-1). Illinois has a special regulation for wet corn mills, and Indiana sets particulate matter emission limits on a case-by-case basis for soybean oil mills and wet corn mills. New Mexico and Utah set particulate matter emission limits for all plants on a case-by-case basis.

12. SPONSORING AGENCY NAME AND ADDRESS U.S. Environmental Protection Agency Office of Air Quality Planning and Standards Emission Standards and Engineering Division Research Triangle Park, North Carolina 27711		10. PROGRAM ELEMENT NO.	
		11. CONTRACT/GRANT NO. 68-02-3059	
13. TYPE OF REPORT AND PERIOD COVERED Final		14. SPONSORING AGENCY CODE EPA/200/04	
15. SUPPLEMENTARY NOTES			
16. ABSTRACT This report presents the findings of a study to assess the need for new source performance standards (NSPS) for animal feed dryers. Industries which use animal feed dryers are included in SIC 2046: Wet Corn Milling; SIC 2047: Dog, Cat, and Other Pet Food; SIC 2048: Prepared Feeds and Feed Ingredients for Animals and Fowls; SIC 2063: Beet Sugar; SIC 2075: Soybean Oil Mills; SIC 2077: Animal and Marine Fats and Oils; SIC 2082: Malt Beverages; and SIC 2085: Distilled, Rectified, and Blended Liquors. Information and estimates concerning production, growth, industry structure, and emissions are presented. Animal feed dryers are sources of particulate matter emissions at plants where they are used. Methods of air pollution control and their effectiveness are examined. Summary of State regulations applicable to dryers is given. An estimate of total emission reduction achievable through an NSPS is given.
