**PM<sub>10</sub>/PM<sub>2.5</sub> EMISSION FACTOR TESTING**  
**for the PULVERIZED MINERAL DIVISION of the**  
**NATIONAL STONE SAND AND GRAVEL ASSOCIATION**

## **1. SUMMARY**

### **1.1 EMISSION FACTOR TEST RESULTS**

The Pulverized Materials Division (PMD) of the National Stone, Sand, and Gravel Association (NSSGA) has retained Air Control Techniques, P.C. to accurately measure PM<sub>10</sub> and PM<sub>2.5</sub> particulate matter emissions from a set of pulverized material processing systems. These tests were part of the NSSGA program initiated in 1991 to determine emission factors for the stone, sand, and gravel industries. Seven pulverized material processing systems at four plants were selected in order to provide a representative sample of the products produced and the processing equipment used by PMD-NSSGA member companies.

The results of the PMD-sponsored emission factor tests have been categorized into four major types of sources: (1) grinding, (2) classifying, (3) drying, and (4) storage. The measured emission factors for total filterable particulate matter, PM<sub>10</sub> filterable particulate matter, and PM<sub>2.5</sub> filterable particulate matter are summarized in Table 1.

| Table 1. Summary of Emission Factor Test Results |                                 |                                               |                                               |                                                |

| 5                                                | Classifier                      | 0.0255                                        | 0.0104                                        | 0.0041                                         |
| 6                                                | Flash Dryer                     | 0.0306                                        | 0.0146                                        | 0.0083                                         |
| 7                                                | Product Storage                 | 0.0063                                        | 0.0016                                        | 0.0006                                         |

All of the particulate matter emissions measured during the study are characteristic of well operated and maintained sources controlled by fabric filters. The emission factors calculated based on the measured emissions are low.

PM<sub>10</sub> filterable particulate matter is approximately 25% to 87% of the total filterable particulate matter for the total set of sources evaluated. PM<sub>2.5</sub> filterable particulate matter represents 9 to 41% of the total filterable particulate matter.

These data will be compiled with other previous emissions tests (total filterable particulate matter emissions) to prepare draft technical materials for future inclusion in EPA's AP-42 emission factor database. The draft AP-42 materials will be prepared and submitted to PMD in the near future.

## 1.2 PLANTS AND PROCESS EQUIPMENT SYSTEMS TESTED

The plants and process equipment systems included within the scope of this testing program were selected by PMD member companies. The four plants and seven systems listed in Table 2 represent a moderate-to-large fraction of the total pulverized materials industry in the U.S.

| Table 2 Host Facilities, Products and Equipment Tested |                |               |                      |                                       |
|--------------------------------------------------------|----------------|---------------|----------------------|---------------------------------------|
| Company Name                                           | Town           | State         | Product Tested       | Equipment Tested                      |
| Polar Minerals, Inc.                                   | Wellsville     | Ohio          | Talc                 | Grinding<br>(Roller Mill)             |
| Specialty Minerals, Inc                                | North<br>Adams | Massachusetts | Calcium<br>Carbonate | Product Silo                          |
| Specialty Minerals, Inc                                | North<br>Adams | Massachusetts | Calcium<br>Carbonate | Classifier                            |
| Specialty Minerals, Inc                                | North<br>Adams | Massachusetts | Calcium<br>Carbonate | Grinding<br>(Raymond Mill)            |
| OMYA, Inc                                              | Florence       | Vermont       | Calcium<br>Carbonate | Flash Dryer                           |
| J. M. Huber<br>Corporation                             | Quincy         | Illinois      | Limestone            | Grinding<br>(Horizontal Ball<br>Mill) |
| J. M. Huber<br>Corporation                             | Quincy         | Illinois      | Barite               | Grinding<br>(Vertical Ball<br>Mill)   |

The emphasis in the testing program was placed on grinding systems because these are of central importance in the production of pulverized materials. The grinding equipment used in the pulverized material industry is quite different from the cone and impact crushers used in stone, sand, and gravel plants. The particle size ranges of products provided by PMD member companies range from less than 75 micrometer material (< 200 mesh) to products having mass mean diameters less than 5 micrometers in diameter. Conventional pulse jet and single compartment reverse air fabric filters control all grinding equipment used in the pulverized materials industry.

Other sources within the scope of this study included a classifier, a dryer, and a product storage silo. Classifiers separate minerals by size and return oversize material for additional grinding. Dryers prepare raw materials for grinding. Silos are used to store finely ground material prior to shipment.

The production levels common to the pulverized materials industry are considerably smaller than the levels in the stone, sand, and gravel industries. PMD member company sources tested as part of this study had processing equipment throughput rates ranging from 0.5 to 14 tons per hour. This is approximately 1/100 to 1/200th of the production levels in crushed stone, sand and gravel plants.

During each of the test programs, Air Control Techniques, P.C. obtained production rate data for each of the processes tested. Detailed process data were not obtained because the pulverized materials industry is highly competitive and process data are considered confidential. The tests were conducted when the equipment was operating near full capacity. During the field tests, the production rates were monitored by plant personnel in order to verify representative plant operations

### 1.3 EMISSION TESTING PROCEDURES

Air Control Techniques, P.C. used draft EPA reference method 201B (available at [www.epa.gov/ttn/emc/](http://www.epa.gov/ttn/emc/)) for the measurement of particulate matter in the PM<sub>2.5</sub> size range. This method has been fully reviewed by EPA and is presently the only recognized method for the measurement of PM<sub>2.5</sub>. There are no alternative techniques under development at EPA. This test method is an extension of Method 201 for the measurement of PM<sub>10</sub> and is based, in part, on EPA research conducted in the mid-1980s. The specific procedures used in draft Method 201B are based on the PM<sub>10</sub>/PM<sub>2.5</sub> emission testing protocol developed by Air Control Techniques, P.C. for the Portland Cement Association (PCA) and published as PCA research publication 2081 (1996).

Method 201 B is a cascade cyclone technique. The Method 201B sampling system consists of the PM<sub>10</sub> cyclone from Method 201A followed by a PM<sub>2.5</sub> cyclone. A 47millimeter (mm) filter is mounted after the PM<sub>2.5</sub> cyclone to collect particles equal to or smaller than 2.5 micrometers (aerodynamic diameter). Particulate matter obtained during sampling is divided into the following three size categories.

- Supercoarse particulate matter having aerodynamic diameters larger than 10 micrometers
- Coarse particulate matter having aerodynamic diameters larger than 2.5 micrometers and equal to or smaller than 10 micrometers
- Fine particulate matter having aerodynamic diameters equal to or smaller than 2.5 micrometers (commonly termed PM<sub>2.5</sub> particulate matter)

The capability of draft Method 201B to separate particulate matter in these three size categories is especially important considering the recent Supreme Court ruling in *American Trucking versus EPA*. As a result of that case, EPA is considering revising the National Ambient Air Quality Standards to independently regulate fine and coarse particulate matter. The emission factor data obtained by means of Method 201B are compatible with both EPA's prior regulatory approach and with the anticipated separate standards for fine and coarse particulate matter.

These data are being provided to PMD to support the development of an emission factor database concerning PM<sub>10</sub> and PM<sub>2.5</sub> emissions for pulverized mineral plants. There are presently no PM<sub>10</sub> and PM<sub>2.5</sub> emission factor data in U.S. EPA Publication AP-42 concerning these types of sources.

## 2. EMISSION TEST RESULTS

### 2.1 CALCIUM CARBONATE RAYMOND MILL PARTICULATE MATTER EMISSIONS

Air Control Techniques, P.C. tested a Raymond Mill baghouse stack at the Specialty Minerals, Inc. North Adams, Massachusetts plant on August 16, 2001. The Raymond mill is used to grind calcium carbonate to sizes less than 80 micrometers. A conventional pulse jet fabric filter is used for particulate matter control.

A sketch of the sampling location for the Raymond Mill is shown in Figure 1. A set of three ports was oriented vertically on the rectangular duct. The ports were located 25 inches upstream of the termination of the duct and more than 60 inches downstream of the closest flow disturbance. This port location satisfied U.S. EPA Method 1 siting requirements.

Figure 1. Calcium Carbonate Raymond Mill Stack Test Port Location

Provisions were made to produce a 3 by 4 sampling matrix to facilitate testing with the Method 201B dual cyclone assembly. The number and location of the sampling and traverse points were determined according to the procedures outlined in EPA Reference Method 1 based on 12 sampling points. The 10.875 inch by 12.5 inch square stack was divided into 12 equal areas with 4 sampling points per each of the three sample axes. A base time of 120 minutes was used for the Method 201B test runs. As required by Method 201B, each point was sampled for a different period of time (dwell time) calculated based on the stack gas velocity of that point.

Prior to sampling, a cyclonic flow check was performed on the calcium carbonate Raymond Mill stack location. The average flow angle measured in the stack was 1.9 degrees. In accordance with Section 2.5.1 of CFR 40 Part 60, special testing procedures to compensate for cyclonic flow are not required unless the average flow angle is in excess of 20 degrees. Therefore, standard testing procedures were used to complete the sampling. The particulate matter emissions measured at the calcium carbonate Raymond Mill are summarized in Table 3.

| Table 3. Calcium Carbonate Raymond Mill Stack Emissions |             |             |             |                   |

| Grains/DSCF                                             | 0.00076     | 0.00071     | 0.00055     | 0.00067           |
| PM <sub>2.5</sub> Cyclone Cut Size, micrometers         | 2.3         | 2.42        | 2.40        | 2.37              |
| Flue Gas Flow, DSCFM                                    | 1,596       | 1,529       | 1,415       | 1,513             |
| Flue Gas Flow, ACFM                                     | 1,909       | 1,840       | 1,739       | 1,829             |
| Moisture, %                                             | 3.60        | 2.72        | 4.09        | 3.47              |
| Stack Temperature, °F                                   | 136.4       | 145.6       | 149.6       | 143.9             |

As indicated in Table 3, all three categories of particulate matter emissions remained at consistently low levels during the three run tests. The total filterable particulate matter concentrations expressed as grains per DSCF are characteristics of well designed, operated, and maintained fabric filter controlled sources. Gas flow rates, moisture levels, and gas temperatures also remained very consistent throughout the test program.

The gas velocities in the exhaust stack averaged 2,016 feet per minute. While this average velocity is low compared to many other industrial sources, no problems were experienced in achieving the particle cut size ( $10 \pm 1.0$  micrometers and  $2.5 \pm 0.25$  micrometer) requirements. All three of the tests were conducted in the required isokinetic range of 80% to 120%. Air Control Techniques, P.C. believes that the data summarized in Table 3 provide an accurate measurement of particulate matter emissions from the process tested.

## 2.2 TALC ROLLER MILL PARTICULATE MATTER EMISSIONS

Air Control Techniques, P.C. tested a talc roller mill baghouse stack at the Polar Minerals, Inc. Wellsville, Ohio Plant on July 7, 2001. Talc is hydrous magnesium silicate that is finely ground for use as a raw material ingredient in paper, rubber, textile, cosmetic, and paint industries. The production rates for the roller mill tested as part of this testing program was 5.67 tons per hour. The particle size range of the material produced by the roller mill was predominately less than 325 mesh. The roller mill was controlled by a conventional pulse jet fabric filter with a design air-to-cloth ratio less than 4 (ft<sup>3</sup>/min per ft<sup>2</sup>).

Figure 2 is a sketch of the talc roller mill stack location. The test ports were located 27 inches downstream of the fan discharge and more than ten duct diameters upstream of the end of the duct. The downstream separation distance of 27 inches was slightly smaller than required by Method 1; however, an evaluation of the point-to-point variations in velocity pressures indicated that the port location did not affect the testing results. There were no reasonable alternatives for the port location. Most of the duct section shown in Figure 2 was elevated and in an inaccessible location.

Figure 2. Talc Roller Mill Stack Test Port Location

Plant personnel installed two 3 inch diameter test ports 90° from one another to facilitate testing with the Method 201B dual cyclone assembly. The number and location of the sampling and traverse points were determined by Air Control Techniques, P.C. according to the procedures outlined in EPA Reference Method 1 based on 12 sampling points. The 16 inch diameter stack was divided into 12 equal areas with 6 sampling points on each of the 2 axes. A base time of 120 minutes was used for the Method 201B test runs. As required by Method 201B, each point was sampled for a different period of time (dwell time) calculated based on the stack gas velocity of that point.

Prior to sampling, a cyclonic flow check was performed on the talc roller mill stack location. The average flow angle measured in the stack was 1.6 degrees. In accordance with Section 2.5.1 of CFR 40 Part 60, special testing procedures to compensate for cyclonic flow are not required unless the average flow angle is in excess of 20 degrees; therefore, standard testing procedures were used to complete the sampling. The particulate emissions measured at the stack are summarized in Table 4.

| Table 4. Talc Roller Mill Stack Emissions       |                      |             |             |                   |

| Grains/DSCF                                     | 0.00343              | 0.00251     | 0.00272     | 0.00289           |
| PM <sub>10</sub> Particulate Emissions          |                      |             |             |                   |
| Pounds/hour                                     | 0.06772              | 0.04621     | 0.04368     | 0.05254           |
| Grains/DSCF                                     | 0.00175              | 0.00119     | 0.00104     | 0.00133           |
| PM <sub>10</sub> Cyclone Cut Size, micrometers  | 10.70                | 10.92       | 10.35       | 10.66             |
| PM <sub>2.5</sub> Particulate Emissions         |                      |             |             |                   |
| Pounds/hour                                     | 0.00912              | 0.00792     | 0.00899     | 0.00868           |
| Grains/DSCF                                     | 0.00024              | 0.00020     | 0.00021     | 0.00022           |
| PM <sub>2.5</sub> Cyclone Cut Size, micrometers | 2.41                 | 2.51        | 2.25        | 2.39              |
| Flue Gas Flow, DSCFM                            | 4,513                | 4,547       | 4,903       | 4,654             |
| Flue Gas Flow, ACFM                             | 5,715                | 5,844       | 5,956       | 5,838             |
| Moisture, %                                     | 3.60                 | 3.05        | 3.33        | 3.33              |
| Stack Temperature, °F                           | 174.0                | 187.0       | 149.9       | 170.3             |

All three of the test runs were very consistent. There were only minimal variations in the total filterable particulate matter concentrations, PM<sub>10</sub> concentrations, PM<sub>2.5</sub> concentrations, gas flow rates, and gas moisture levels. All of the particulate matter emissions were quite low.

The Method 201B tests satisfied all applicable quality assurance requirements with the exception of Method 1 requirements for port location.

All of the Method 201B tests at the Wellsville plant achieved the particle cut size requirements ( $10 \pm 1.0$  micrometers and  $2.5 \pm 0.25$  micrometer). All three of the tests were conducted in the required isokinetic range of 80% to 120%. Air Control Techniques, P.C. believes that the data summarized in Table 4 provide an accurate measurement of particulate matter emissions from the process tested.

### 2.3 LIMESTONE HORIZONTAL BALL MILL PARTICULATE MATTER EMISSIONS

Air Control Techniques, P.C. tested a horizontal ball mill baghouse stack at the J.M. Huber Corporation, Quincy, Illinois plant on September 5, 2001. A conventional grinding system is used to reduce mineral material to sizes less than 325 mesh. The ball mill is used for pulverizing limestone. The effluent gas stream from the ball mill is controlled by a pulse jet fabric filter having a design air-to-cloth ratio less than 4 (ft<sup>3</sup>/min per ft<sup>2</sup>).

The sampling location for this system was a set of test ports located on a horizontal duct on the fan discharge. As shown in Figure 3, the ports were located more than two duct diameters downstream of the fan discharge and more than two duct diameters upstream of the termination of the duct. This port location complies with U.S. EPA Method 1 guidelines. Air Control Techniques, P.C. used a 2 by 6 sampling matrix during testing with the Method 201B dual cyclone assembly. The number and location of the sampling and traverse points were determined according to the procedures outlined in EPA Reference Method 1. The 12 inch by 12-inch square stack was divided into 12 equal areas with 6 sampling points per sample axes. A base time of 120 minutes was used for the Method 201B test runs. As required by Method 201B, each point was sampled for a different period of time (dwell time) calculated based on the stack gas velocity of that point.

Figure 3. Limestone Horizontal Ball Mill Stack Test Port Location

Prior to sampling, a cyclonic flow check was performed on the horizontal ball mill stack location. The average flow angle measured in the stack was 1.7 degrees. In accordance with Section 2.5.1 of CFR 40 Part 60, special testing procedures to compensate for cyclonic flow are not required unless the average flow angle is in excess of 20 degrees; therefore, standard testing procedures were used to complete the sampling.

The particulate matter emissions and emission factors measured at the horizontal ball mill stack are summarized in Table 5.

| Table 5. Limestone Horizontal Ball Mill Stack Emissions |              |              |              |                   |

Air Control Techniques, P.C. experienced no problems in achieving the particle cut size requirements ( $10 \pm 1.0$  micrometers and  $2.5 \pm 0.25$  micrometer). All three of the tests were conducted in the required isokinetic range of 80% to 120%. Air Control Techniques, P.C. believes that the data summarized in Table 5 provide an accurate measurement of particulate matter emissions from the horizontal ball mill.

## 2.4 BARITE VERTICAL BALL MILL PARTICULATE MATTER EMISSIONS

Air Control Techniques, P.C. tested a vertical ball mill baghouse stack at the J.M. Huber Corporation, Quincy, Illinois Plant on September 6, 2001. This is a conventional grinding system used to reduce mineral material from a feed size of less than 10 micrometers to a product size with a mass median diameter in the range of 2 to 3 micrometers. This is the smallest sized product material included in the scope of this emission factor testing projects. PMD representatives need to determine if this type of process is representative of (1) the other three types of grinding operations included in this study and (2) other processes used in the pulverized materials industry. The ball mill is used for pulverizing barite, a mineral composed primarily of barium sulfate. The effluent gas stream from the ball mill is controlled by a pulse jet fabric filter having a design air-to-cloth ratio less than 4 (ft<sup>3</sup>/min per ft<sup>2</sup>).

A sketch of the test ports for this system is shown in Figure 4. The ports were located 196 inches downstream of the descending elbow from the fabric filter and more than 44 inches upstream of the elbow leading to the centrifugal fan for the system. This port location satisfies U.S. EPA Method 1 siting requirements.

Two 5 inch diameter test ports were installed 90 degrees from one another to facilitate testing with the Method 201B dual cyclone assembly. The number and location of the sampling and traverse points were determined according to the procedures outlined in EPA Reference Method 1 based on 12 sampling points. The 18 inch diameter stack was divided into 12 equal areas with 6 sampling points on each of the 2 axes. A base time of 120 minutes was used for the Method 201B test runs. Each point was sampled for a different period of time (dwell time) calculated based on the stack gas velocity of that point.

Figure 4. Barite Vertical Ball Mill Test Port Location

Prior to sampling, a cyclonic flow check was performed on the barite vertical ball mill stack location. The average flow angle measured in the stack was 2.0 degrees. In accordance with Section 2.5.1 of CFR 40 Part 60, special testing procedures to compensate for cyclonic flow are not required unless the average flow angle is in excess of 20 degrees; therefore, standard testing procedures were used to complete the sampling. The particulate matter emissions measured at the barite vertical ball mill are summarized in Table 6.

| Table 6. Barite Vertical Ball Mill Stack Emissions |              |              |              |                   |

The total filterable particulate matter emissions from the vertical ball mill averaged 0.0167 grains/ACF. While this emission rate is characteristic of a properly operating fabric filter control system, the particulate matter emissions are well above those observed in other sources. Air Control Techniques, P.C. believes that the grinding source to grinding source differences could be due to (1) inherent bag cleaning difficulties associated with the extremely small product size or (2) non-ideal fabric filter operating conditions at the time of the emission factor tests. Air Control Techniques, P.C. has requested previously conducted total filterable particulate matter test results for this source to evaluate if the tests conducted on September 6, 2001 are representative of this facility. Air Control Techniques, P.C. has also requested additional emission tests from the other three grinding system tested to further evaluate the representativeness of these tests. The results of the comparisons with previous emission tests will be summarized in letter report to be submitted to PMD after these historical tests are received and reviewed.

## 2.5 CALCIUM CARBONATE CLASSIFIER PARTICULATE MATTER EMISSIONS

Air Control Techniques, P.C. tested the classifier system at Specialty Minerals, Inc. North Adams, Massachusetts plant on August 15, 2001. The calcium carbonate classifier tested as part of this emission factor compilation program was used to separate particulate matter in the 20 to 80 micrometer size range. The effluent gas stream was treated in a conventional pulse jet fabric filter with a design air-to-cloth ratio less than 4 (ft<sup>3</sup>/min per ft<sup>2</sup>).

Figure 5. Calcium Carbonate Classifier Stack Test Port Location

The test port location shown in Figure 5 satisfies all U.S. EPA Method 1 siting requirements. Three 5 inch diameter test ports were installed in the square stack to facilitate testing with the Method 201B dual cyclone assembly. The number and location of the sampling and traverse points were determined according to the procedures outlined in EPA Reference Method 1 based on 12 sampling points. The 24 inch square stack was divided into 12 equal areas with 4 sampling points per sample port. A base

time of 120 minutes was used for the Method 201B test runs. As required by Method 201B, each point was sampled for a different period of time (dwell time) calculated based on the stack gas velocity of that point.

Prior to sampling, a cyclonic flow check was performed on the calcium carbonate classifier stack location. The average flow angle measured in the stack was 0.0 degrees. In accordance with Section 2.5.1 of CFR 40 Part 60, special testing procedures to compensate for cyclonic flow are not required unless the average flow angle is in excess of 20 degrees; therefore, standard testing procedures were used to complete the sampling. The particulate emissions measured at the calcium carbonate classifier are summarized in Table 7

| Table 7. Calcium Carbonate Classifier Stack Emissions |             |             |             |                   |

| Flue Gas Flow, ACFM                                   | 1,689       | 1,495       | 1,567       | 1,584             |
| Moisture, %                                           | 1.02        | 1.22        | 1.14        | 1.13              |
| Stack Temperature, °F                                 | 115.5       | 128.6       | 136.1       | 126.7             |

The measured emissions of total filterable particulate matter, PM<sub>10</sub> particulate matter, and PM<sub>2.5</sub> particulate matter were very consistent and very low. These emissions are characteristic of a well designed, operated, and maintained fabric filter control system for a classifier.

All of the Method 201B tests at the North Adams plant achieved the particle cut size requirements ( $10 \pm 1.0$  micrometers and  $2.5 \pm 0.25$  micrometer). All three of the tests were conducted in the required isokinetic range of 80% to 120%. Air Control Techniques, P.C. believes that the data summarized in Table 2-3 provide an accurate measurement of particulate matter emissions from the process tested.

## 2.6 CALCIUM CARBONATE FLASH DRYER PARTICULATE MATTER EMISSIONS

Air Control Techniques, P.C. tested a flash dryer baghouse stack at the OMYA, Inc. Florence, Vermont plant on August 17, 2001. The flash dryer is used to dry calcium carbonate feed material prior to grinding. The dryer is fired with No. 2 oil. The dryer throughput rates during the tests averaged approximately 11.08 tons per hour. The dryer was controlled by a conventional pulse jet fabric filter with a design air-to-cloth ratio less than 4 (ft<sup>3</sup>/min per ft<sup>2</sup>).

This source had the highest gas flow rate of the set of seven sources tested as part of this emission factor compilation program. At an average flow rate of 20,524 ACFM, this source had gas flows that were larger than the combined flows from the other six sources tested. The moisture levels and the gas temperatures were also considerably higher than the other sources tested.

The test ports for the flash dryer are located in a stack discharging the effluent gas stream from a baghouse and a centrifugal fan. The location of the test ports shown in Figure 6 fully satisfied all Method 1 requirements. There were two 4 inch diameter test ports located 90 degrees° from one another to facilitate testing. The 30 inch diameter stack was divided into 12 equal areas with 6 sampling points on each of the 2 axes. A base time of 120 minutes was used for the Method 201B test runs. As required by Method 201B, each point was sampled for a different period of time (dwell time) calculated based on the stack gas velocity at that point.

Figure 6. Calcium Carbonate Flash Dryer Stack Test Port Location

Prior to sampling, a cyclonic flow check was performed. The average flow angle measured in the stack was 4.2 degrees, well with the 20 degree limited specified in Section 2.5.1 of CFR 40 Part 60; therefore, standard testing procedures were used to complete the sampling. The particulate matter emissions measured at the calcium carbonate flash dryer are summarized in Table 8.

The particulate matter emissions measured in all three runs at this facility were consistently low. The outlet grain loadings of less than 0.005 grains per ACF observed in these tests are representative of well designed, operated, and maintained fabric filter control systems.

Air Control Techniques, P.C. experienced no problems in achieving the particle cut size requirements ( $10 \pm 1.0$  micrometers and  $2.5 \pm 0.25$  micrometer). All three of the tests were conducted in the required isokinetic range of 80% to 120%. Air Control Techniques, P.C. believes that the data summarized in Table 7 provide an accurate measurement of particulate matter emissions from the flash dryer.

| Table 8. Calcium Carbonate Flash Dryer Stack Emissions |             |             |             |                                |

## 2.7 CALCIUM CARBONATE PRODUCT SILO PARTICULATE MATTER EMISSIONS

Air Control Techniques, P.C. tested a product silo baghouse stack at the Specialty Minerals, Inc. North Adams, Massachusetts plant on August 14, 2001. The product is a finely ground calcium carbonate (limestone) with a mass median diameter less than approximately 50 micrometers. Particulate matter is emitted from the silo due to displaced air movement during product loading and unloading from the silo. The emissions are controlled by a small displaced air fabric filter system.

Figure 7. Calcium Carbonate Product Silo Stack Test Port Location

As indicated in Figure 7, the test port was approximately 1 diameter upstream of an elbow. Due to the close proximity of a flow disturbance, this location does not satisfy Method 1 guidelines. An inspection of the ductwork indicated that there were no reasonable alternatives to this location. The velocity pressure data indicated that the disturbance did not significantly affect the test results.

Two 4 inch diameter test ports were installed 90 degrees° from one another to facilitate testing with the Method 201B dual cyclone assembly. The number and location of the sampling and traverse points were determined according to the procedures outlined in EPA Reference Method 1 based on 12 sampling points. The relatively small 12.25 inch diameter stack was divided into 12 equal areas with 6 sampling points on each of the 2 axes. A base time of 120 minutes was used for the Method 201B test runs. Each point was sampled for a different period of time (dwell time) calculated based on the stack gas velocity of that point.

Prior to sampling, a cyclonic flow check was performed on the calcium carbonate product silo stack location. The average flow angle measured in the stack was 1.0 degrees. In accordance with Section 2.5.1 of CFR 40 Part 60, special testing procedures to compensate for cyclonic flow are not required unless the average flow angle is in excess of 20 degrees; therefore, standard testing procedures were used to complete the sampling. The particulate emissions measured at the calcium carbonate product silo are summarized in Table 9.

| Table 9. Calcium Carbonate Product Silo Stack Emissions |             |             |             |                   |

| Moisture, %                                             | 1.54        | 1.80        | 1.80        | 1.71              |
| Stack Temperature, °F                                   | 81.8        | 87.5        | 86.7        | 85.3              |

As with most product storage silos, the gas flow rates from the silo are very low. The gas velocities in the 12.5 inch diameter stack were extremely low, 627 to 649 feet per second. This velocity range is well below the values typical of most air pollution control systems. These low velocities are also below the normal velocities encountered in PM<sub>10</sub> testing using Method 201A and in PM<sub>10</sub>/PM<sub>2.5</sub> testing using Method 201B. Despite these very challenging velocity conditions, Air Control Techniques, P.C. was able to satisfy the Method 201B cut size requirements. The isokinetic conditions were intentionally set above the 120% levels in order to achieve the cut size requirements.

All of the particulate matter emissions measured from this source are extremely low and are characteristic of a very well controlled source. While there are some run-to-run variations, these differences are insignificant considering the extremely low levels observed in all three test runs.

All of the Method 201B tests at the North Adams Plant achieved the particle cut size requirements ( $10 \pm 1.0$  micrometers and  $2.5 \pm 0.25$  micrometer). Air Control Techniques, P.C. believes that the data summarized in Table 9 provide an accurate measurement of particulate matter emissions from the process tested.

The duration of run #3 at the North Adams product silo was longer than the normal two hour testing period. This extended testing time was due to a process interruption.

## 2.8 PRODUCTION DATA

The appendix to of this report contains production data from the processes tested. These data were supplied by plant personnel. A summary of the production data is presented in Table 10 to demonstrate that the emission tests were conducted under representative operating conditions, and that the production data were used in the calculation of emission factors.

| Table 10. Host Facilities Production and Material Data |                  |                            |                   |                                 |

## 2.9 EMISSION FACTOR RESULTS

Emission factors for the various sources tested have been calculated based on the emissions data in Sections 2-1 to 2-7 and the production rates in Section 2-8. These emission factors have been presented in units of pounds of particulate matter per ton of product. This is consistent with the emission factor format for mineral product industries included in EPA's AP-42 database (Section 11.19). The total filterable particulate emission factors for the seven sources tested are summarized in Figure 8.

Figure 8. Total Filterable Particulate Emission Factors

The PM<sub>10</sub> and PM<sub>2.5</sub> emission factors for these seven sources are summarized in Figures 9 and 10. It is apparent from the similarity of these two charts that the PM<sub>10</sub> and PM<sub>2.5</sub> emission factors are very similar. The PM<sub>10</sub> measured during the test program that was in the PM<sub>2.5</sub> size fraction ranges from 17% to 55% with an average of 41%. This is illustrated in Figure 11, which provides a comparison of these two data sets.

The PM<sub>2.5</sub> particulate matter comprised 8% to 41% with an average of 22% of the total filterable particulate matter as measured using Method 201B. The differences between these two categories of particulate matter are shown in Figure 12.

The PM<sub>10</sub> particulate matter comprised 25% to 87% with an average of 52% of the total filterable particulate matter as measured using Method 201B. The differences between these two categories of particulate matter are shown in Figure 13.

Figure 9. Filterable PM<sub>10</sub> Emission FactorsFigure 10. Filterable PM<sub>2.5</sub> Emission Factors

Figure 11. Comparison of Filterable PM<sub>2.5</sub> and PM<sub>10</sub> Emission FactorsFigure 12. Comparison of Total Filterable Particulate and PM<sub>2.5</sub> Particulate Emission Factors

Figure 13 Comparison of Total Filterable Particulate and PM<sub>10</sub> Particulate Emission Factors

### 3. SAMPLING AND ANALYTICAL PROCEDURES

#### 3.1 PM<sub>10</sub>/PM<sub>2.5</sub> PARTICULATE EMISSIONS

The sampling system consisted of the PM<sub>10</sub> cyclone from Method 201A followed by the PM<sub>2.5</sub> cyclone from a five stage cascade cyclone train. A 47mm filter was mounted after the PM<sub>2.5</sub> cyclone. The sampling train was identical to Method 201A except that the PM<sub>2.5</sub> cyclone was inserted between the PM<sub>10</sub> cyclone and the filter. Both cyclones and the filter were coupled closely together so that the entire sampling head shown in Figure 14 could be operated in-situ.

Figure 14. Method 201B Sampling Head

As with Method 201A, Method 201B is a constant sampling rate (CSR) technique. It is critical to maintain the actual sample gas flow rate in each of the cyclones at a rate that provides the desirable particle collection efficiencies. Ideally, cyclone I must collect particles that have a D<sub>50</sub> (particle size collected with 50% efficiency) between 9.0 and 11.0 micrometers in order to be consistent with Method 201A. Cyclone IV (the second cyclone in Figure 1) should optimally have a cut diameter between 2.25 and 2.75 micrometers. Using the cyclone performance curves, Air Control Techniques, P.C. has calculated the sampling rates necessary to simultaneously satisfy the cyclone I and cyclone IV D<sub>50</sub> ranges. The area between the two solid lines in Figure 15 demonstrates that this range is reasonably large for sources operating at elevated gas temperatures; however at ambient or near ambient temperature, the range is quit small. Furthermore, it is important to maintain the sampling velocities in the nozzle at a rate between 80% and 120% of the isokinetic velocity.

Two hour sampling times were used to ensure that catch weights of both the PM<sub>10</sub> and PM<sub>2.5</sub> cyclones could be analyzed gravimetrically. These sampling times were considerably longer than the one-hour runs typically used in EPA Methods 5 and 17 for the measurement of total filterable particulate matter. These long sampling times were needed due to the relatively low particulate matter concentrations in the PM<sub>2.5</sub> size range.

Figure 15. Sampling Rate Requirements of Method 201B

Air Control Techniques, P.C. used Method 201B to determine the PM<sub>10</sub>/PM<sub>2.5</sub> particulate matter emissions from all seven sources included in the scope of this testing program. Method 201B and Method 4 were conducted on all of the seven sources in accordance with all applicable EPA sampling and quality assurance requirements. The tests consisted of a set of three runs each per test location.

**Sample Collection.** Samples were withdrawn isokinetically (100%  $\pm$  20%) from the source using a Method 201B sampling train. The sampling train consisted of a nozzle and the dual cyclone configuration followed by a 47mm filter holder (as seen in Figure 14), a stainless steel lined probe with an S Type Pitot tube attached, four chilled impingers, and a metering console. The particulate sample was collected on a glass fiber filter supported by a stainless steel frit.

The combined Method 201B and Method 4 sample train contained 100 ml of ml of deionized, distilled (DI) water in the first two impingers, the third was empty, and the fourth contained preweighed silica gel.

**Sample Recovery.** The combined cyclone sampling head was recovered using a nylon brush and ultra-pure acetone rinse. The particulate was divided into four separate sample jars.

Sample Jar #1: Particulate Matter > 10 micrometers

- Solids and acetone rinse from cyclone I cup
- Acetone rinse of nozzle
- Acetone rinse of cyclone I

Sample Jar #2: Particulate Matter ≤ 10 micrometers and > 2.5 micrometers

- Cyclone I turnaround cup (above inner downcomer line)
- Brushed and acetone rinsed solids from downcomer line
- Solids from cyclone IV cup
- Acetone rinse of cyclone IV

Sample Jar #3: Particulate Matter ≤ 2.5 micrometers

- Brushed and acetone rinsed solids from downcomer line
- Acetone rinse from front half of filter holder

Sample Jar #4, Particulate Matter ≤ 2.5 micrometers

- Filter

The total filterable particulate matter is the sum of all the particulate matter recovered from the combined cyclone sampling assembly. PM<sub>10</sub> particulate matter is all of the solids recovered from sample jars #2, #3, and #4. PM<sub>2.5</sub> particulate matter is determined based on the quantity of solids recovered from sample jars #3 and #4. An acetone blank was analyzed and subtracted from the particulate catch weights using the volume of acetone rinse used for each sample jar.

The DI water reagent was returned to the original 1000 ml glass jar and weighed. The weight was recorded on the label, and the liquid level was marked. The silica gel was returned to the original tared container and weighed. The weight was recorded on the label. The volume of water vapor condensed in the impingers and the volume of water vapor collected in the silica gel were summed and entered into moisture content calculations.

**Sample Analyses.** EPA Method 5 analytical procedures were used to analyze the filter and three front half acetone rinses for particulate matter.

## 3.2 GENERAL U.S. EPA REFERENCE TEST METHODS

### 3.2.1 Sampling Point Determination - EPA Method 1

The number and location of the sampling and traverse points used in the Method 201B tests were determined according to the procedures outlined in U.S. EPA Reference Method 1, based on 12 sampling points. Sampling points located less than 1.0 inch from the stack wall were relocated to 1.0 inch from the wall as required by the method. This was important to avoid biasing the results due to dislodging and capturing wall deposits by the sampling probe.

### 3.2.2 Flue Gas Velocity and Volumetric Flow Rate - EPA Method 2

The flue gas velocity and volumetric flow rate during the Method 201B tests were determined according to the procedures outlined in U.S. EPA Reference Method 2. Velocity measurements were made using S-Type pitot tubes conforming to the geometric specifications outlined in Method 2. Accordingly, each pitot was assigned a coefficient of 0.84. Velocity pressures were measured with

fluid manometers. An electronic micro-manometer was used on the classifier stack due to extremely low flue gas velocities of 7 feet per second. Effluent gas temperatures were measured with chromel-alumel thermocouples equipped with digital readouts. A cyclonic flow check was performed prior to the Method 201B tests at each sampling location.

### **3.2.3 Flue Gas Composition and Molecular Weight - EPA Method 3**

Flue gas analyses and calculation of flue gas dry molecular weight were performed in accordance with EPA Method 3. Multi-point, integrated sampling was used to obtain a flue gas sample concurrent with isokinetic testing. A stainless steel probe was affixed to the isokinetic sampling probe for this purpose. A squeeze aspirator was used to draw a sample. Moisture was removed from the sample gas by means of a knockout jar located prior to the aspirator. Oxygen and carbon dioxide were determined using a Fyrite® apparatus.

### **3.2.4 Flue Gas Moisture Content - EPA Method 4**

The flue gas moisture contents during the Method 201B tests were determined in conjunction with each sample train according to the sampling and analytical procedures outlined in EPA Method 4. The impingers were connected in series and contained reagents as listed in the method descriptions in section 3.2.1 of this report. The impingers were contained in an ice bath to assure condensation of the flue gas stream moisture. Any moisture that was not condensed in the impingers was captured in the silica gel; therefore all moisture could be weighed and entered into moisture content calculations.

## **4. QUALITY ASSURANCE AND QUALITY CONTROL**

### **4.1 QA/QC SUMMARY**

All of the tests were conducted using QA/QC procedures established by the EPA and Air Control Techniques, P.C. for Method 201B. Complete records concerning the QA/QC procedures were prepared during the tests. Problems encountered before a test run were identified and corrected prior to sampling. Problems at the conclusion of a test run were identified and brought to the attention of the plant project manager, and a determination of the acceptability of the run was made.

#### **4.1.1 Leak Checks**

Pretest and posttest leak checks were conducted on each sampling train used in all Method 201B tests. The observed leak rates were below 0.02 actual cubic feet per minute and, therefore, were acceptable. Posttest leak checks were completed with the dual cyclone removed. This is a standard Method 201A procedure to ensure that the particles in the cyclone catch cups are not re-entrained into subsequent stages.

#### **4.1.2 S-Type Pitot Tube Calibration**

All S-Type pitot tubes used in this project conformed to EPA guidelines concerning construction and geometry. Pitot tubes were inspected prior to use. The specified guidelines were met; therefore, a pitot tube coefficient of 0.84 was used. Information pertaining to S-type pitot tubes is presented in detail in Section 3.1.1 of EPA Publication No. 600/4-77-027b. Only S-type pitot tubes meeting the required EPA specifications were used in this project.

#### **4.1.3 Sample Nozzle Calibration**

Stainless steel nozzles were used for isokinetic sampling. All nozzles were thoroughly cleaned, visually inspected, and calibrated on-site prior to sampling according to the procedures outlined in Section 3.4.2 of EPA Publication No. 600/4-77-027b.

#### **4.1.4 Temperature Monitor Calibration**

The thermocouples used in this project were calibrated using the procedures described in Section 3.4.2 of EPA Publication No. 600/4-77-027b. Each temperature sensor was calibrated at a minimum of 3 points over the anticipated range of use against an NIST-traceable mercury in glass thermometer.

#### **4.1.5 Dry Gas Meter Calibration**

All dry gas meters were fully calibrated prior to shipment to the plant to determine the volume correction factor prior to field use. Upon arrival at the plant, a ten minute pre-calibration was performed to verify the full calibration correction factor. The calibration procedure is documented in Section 3.3.2 of EPA Publication No. 600/4-77-237b.

#### **4.1.6 Moisture Scale Calibration**

The scales used in the recovery laboratory to determine flue gas moisture content were calibrated using a standard set of weights.

#### **4.1.7 Particulate Sampling Using Method 201B**

Standard operating procedures described in Draft Method 201B were followed. Prior to conducting the test, the sampling trains were tested to confirm proper operation and to determine the sampling nozzles needed to achieve isokinetic sampling conditions. The gas flow velocities at the sampling locations were measured using EPA Method 2. An S-type pitot tube was used for these velocity measurements. The S-type pitot tube was visually inspected before each run. Each leg of the pitot tube was leak checked before and after each run. Proper orientation of the S-type pitot tube was maintained throughout each measurement. Checks for cyclonic flow were completed at each sampling location before the start of the first test run.

## 4.2 QA/QC CHECKS FOR DATA REDUCTION, VALIDATION, AND REPORTING

Daily quality audits were conducted using data quality indicators that require the review of the recording and transfer of raw data, calculations, and documentation of testing procedures. All data and calculations for air flow rates and isokinetic sampling rates were recorded manually and then transferred to a portable computer. The calculations were verified by independent, manual checks. Any suspect data or outliers were noted and identified with respect to the nature of the problem and potential effect on data quality.

### 4.2.1 Quality Assurance Results

Some of the twenty one Method 201B test runs did not fully satisfy the quality assurance requirements specified by Method 201B. These quality assurance requirements and the results of the test runs are summarized in Table 11. Each of the deviations from the quality assurance requirements is summarized below.

### 4.2.2 Calcium Carbonate Classifier (Runs SM2-M201B-1, 2, and 3)

The calcium carbonate classifier stack has extremely low gas velocities of 6 to 7 feet per second. These velocities are well below typical stack velocities of 30 to 90 feet per second. These velocities are also well below the gas velocity range considered during the development of Method 201B.

Commercially available air emission testing equipment, including the equipment used in this test program, is not designed for these very low velocities. Specifically, sampling nozzles that fit the Cyclone 1 sampling head are not appropriate for this condition. Based on pretest discussions with National Stone, Sand & Gravel personnel, Air Control Techniques, P.C. adjusted the sampling conditions to optimize the D<sub>50</sub> values in both cyclones. This approach maximized the accuracy of the particle size cuts achieved by the cyclones. Air Control Techniques, P.C. believes that the reported data are the most accurate data that could be obtained at these very low velocities.

### 4.2.3 Sample Recovery and Custody

All filter samples and impinger samples were recovered by Air Control Techniques personnel using standard EPA procedures. Sample recovery was performed in mobile laboratories located at each of the plants. All sampling equipment was sealed to prevent contamination during transport to and from the laboratory.

All chemicals used for sampling train preparation and sample recovery were American Chemical Society ACS, High Performance Liquid Chromatography (HPLC) or pesticide grade. Reagent water met or exceeded the American Society for Testing Materials (ASTM) specifications for Type I reagent water.

The samples recovered from each of the reference method tests are listed below.

#### Method 201B

- Sample Jar #1, Particulate Matter > 10 micrometers
- Sample Jar #2, Particulate Matter ≤ 10 micrometers and > 2.5 micrometers
- Sample Jar #3, Particulate Matter ≤ 2.5 micrometers
- Sample Jar #4, Filter Particulate Matter ≤ 2.5 micrometers
- Acetone blank (1 per acetone lot)
- Silica gel (impinger 4 for moisture determination)

Table 11. Method 201B Quality Assurance Results

| Parameter    | Cyclonic flow, degrees | Condenser exit temp., °F | Isokinetics, % | Pre-leak check, DSCFM | Post-leak check, DSCFM | Cut Diameters (D <sub>50</sub> ) µm |                  |

| JMH2-M201B-3 | 2.0                    | <68                      | 83.9           | <0.02                 | <0.02                  | 2.45                                | 10.82            |

All of the samples were labeled immediately after recovery. The samples were packed in boxes and sealed. A chain of custody record and sample log was maintained during the emissions study. The sample boxes were shipped by Air Control Techniques to Cary, N.C. The samples were picked up by Resolution Analytics along with the appropriate chain of custody record forms.

## **Sample Matrix & Components:**

Dry Filters, Acetone Rinses (Precutter/Cyclone and Front<sup>1</sup>/<sub>2</sub> rinses weighed separately), Acetone Blank

## **Summary of Sample Prep:**

The acetone rinses and pre-tared filters were transferred to pre-tared teflon "baggies" in a low humidity environment. The acetone rinses were evaporated overnight, then desiccated for 24 hours, after which time they were weighed daily every six hours until consecutive weights agreed within  $\pm 0.5$  mgs. The filters were oven dried at 105°C for 2 hours and weighed immediately afterwards. All weights were recorded to the nearest 0.1 mg and include filterable particulate catch only. The total catch reported for each run is a sum of the filter and rinse catches. The acetone blank catch has been subtracted out of sample rinse catches in proportion with their respective volumes.

## **Summary of Instrumentation:**

Denver model A-250 analytical balance

Analytical Detection Limit(s): 0.5 mgs

**Miscellaneous Comments Regarding Sample Analysis:** (Note unusual catch weights, interferences, odd sample behavior, and steps taken to confirm unusual results. Also note any deviations from standard analytical procedures, together with justification and possible affect on results. Specify samples when applicable.)

No modifications to EPA Method 5 analytical procedure were made.

See Data Sheets for individual sample descriptions.

# Analytical Narrative

RFA # 642

Page 1 of 1

Client/Plant Name: ACT

Date Rec'd in lab: 8/20/2001

Analyst: CLT

Date of Analysis: 9/7/2001

Analysis Method: EPA Method 201B

Analyte(s): PM <2.5micron

## **Sample Matrix & Components:**

Dry Filters, Acetone Rinses (Precutter/Cyclone and Front<sup>1</sup>/<sub>2</sub> rinses weighed separately), Acetone Blank

## **Summary of Sample Prep:**

The acetone rinses and pre-tared filters were transferred to pre-tared teflon "baggies" in a low humidity environment. The acetone rinses were evaporated overnight, then desiccated for 24 hours, after which time they were weighed daily every six hours until consecutive weights agreed within  $\pm 0.5$  mgs. The filters were oven dried at 105°C for 2 hours and weighed immediately afterwards. All weights were recorded to the nearest 0.1 mg and include filterable particulate catch only. The total catch reported for each run is a sum of the filter and rinse catches. The acetone blank catch has been subtracted out of sample rinse catches in proportion with their respective volumes.

## **Summary of Instrumentation:**

Denver model A-250 analytical balance

Analytical Detection Limit(s): 0.5 mgs

**Miscellaneous Comments Regarding Sample Analysis:** (Note unusual catch weights, interferences, odd sample behavior, and steps taken to confirm unusual results. Also note any deviations from standard analytical procedures, together with justification and possible affect on results. Specify samples when applicable.)

No modifications to EPA Method 5 analytical procedure were made.

See Data Sheets for individual sample descriptions.

## **Confirmation of Data Review:**

# Analytical Narrative

RFA # 642

Page 1 of 1

Client/Plant Name: ACT

Date Rec'd in lab: 9/07/01

Analyst: CLT

Date of Analysis: 9/12/01

Analysis Method: EPA Method 201B

Analyte(s): PM <2.5micron

## **Sample Matrix & Components:**

Dry Filters, Acetone Rinses (Precutter/Cyclone and Front $\frac{1}{2}$  rinses weighed separately), Acetone Blank

## **Summary of Sample Prep:**

The acetone rinses and pre-tared filters were transferred to pre-tared teflon "baggies" in a low humidity environment. The acetone rinses were evaporated overnight, then desiccated for 24 hours, after which time they were weighed daily every six hours until consecutive weights agreed within  $\pm 0.5$  mgs. The filters were oven dried at 105°C for 2 hours and weighed immediately afterwards. All weights were recorded to the nearest 0.1 mg and include filterable particulate catch only. The total catch reported for each run is a sum of the filter and rinse catches. The acetone blank catch has been subtracted out of sample rinse catches in proportion with their respective volumes.

## **Summary of Instrumentation:**

Denver model A-250 analytical balance

Analytical Detection Limit(s): 0.5 mgs

**Miscellaneous Comments Regarding Sample Analysis:** (Note unusual catch weights, interferences, odd sample behavior, and steps taken to confirm unusual results. Also note any deviations from standard analytical procedures, together with justification and possible affect on results. Specify samples when applicable.)

No modifications to EPA Method 5 analytical procedure were made.

See Data Sheets for individual sample descriptions.

## **Confirmation of Data Review:**

EPA Method 5

522 Series Meter Box Calibration

Post-Test Orifice Method

English Meter Box Units, English K' Factor

Filename: \\TODD\c\DRY GAS METER CALS\ACTPC CALIBRATIONS\702233 A-M-1 Calibrations\Post-test Cal\5-03-01.xls

Revised: 7/25/95 Version: 2.2

Model #: 522  
 Serial #: 702233  
 Meterbox Y, (Gamma) 1.002

Date: 5/3/2001  
 Barometric Pressure: 30.30 (in. Hg)  
 Theoretical Critical Vacuum: 14.29 (in. Hg)

!!!!!!!  
 IMPORTANT  
 IMPORTANT  
 IMPORTANT  
 !!!!!!!

For valid test results, the Actual Vacuum should be 1 to 2 in. Hg greater than the Theoretical Critical Vacuum shown above. The Critical Orifice Coefficient, K', must be entered in English units, (ft)<sup>3</sup>\*(deg R)<sup>0.5</sup>/((in.Hg)\*(min)).

IMPORTANT  
IMPORTANT  
IMPORTANT  
!!!!!!!

For valid test results, the Actual Vacuum should be 1 to 2 in. Hg greater than the Theoretical Critical Vacuum shown above. The Critical Orifice Coefficient, K', must be entered in English units, (ft)<sup>3</sup>\*(deg R)<sup>0.5</sup>/((in.Hg)\*(min)).

## **APPENDIX D**

### **Field Data Sheets**

# Method 1 - Air Control Techniques, P.C.

Date

7/16/01

Client PMD  
 Job # 012  
 Plant Name Polar  
 City Wellsville  
 State Ohio  
 Sampling Location Roller Mill Duct

Note: If more than 8 and 2 diameters and if duct dia. is less than 24" use 8 or 9 points.

## Diameters

| Velocity | UP | Down | Particulate |
|----------|----|------|-------------|
| 12       | 8  | 2    | 12          |
| 12       | 7  | 1.75 | 12          |
| 12       | 6  | 1.5  | 16          |
| 16       | 5  | 1.25 | 20          |
| 16       | 2  | 0.5  | 24 or 25    |

No. of Ports Available

2

No. of Ports Used

2

Port Inside Diameter, Inches

3

Distance From Far Wall To Outside Of Port, Inches

20"

Nipple Length And/Or Wall Thickness, Inches

4"

Depth Of Stack Or Duct, Inches

16"

Stack Or Duct Width (if rectangular), Inches

16"

Equiv. Diameter =  $2DW/(D+W)$ , Inches

16"

Stack/Duct Area, Square Inches

( $\pi \times R^2$  or  $L \times W$ )

Upstream

Downstream

Distance to Flow Disturbances

## **APPENDIX F**

### **Plant Production Data**

**Subject: Material throughput in Roller Mill test**

**Date:** Wed, 18 Jul 2001 11:02:32 -0400

**From:** Hector Diaz <Hector.Diaz@polarminerals.com>

**To:** "actpc@aircontroltechniques.com" <actpc@aircontroltechniques.com>

**CC:** Jennifer Dechellis <JenniferD@polarminerals.com>,  
Debbie Ambrose <DebbieA@polarminerals.com>

Dear Todd:

The material throughputs we had while testing for the PM2.5 in Wellsville are as follows:

First test, and 1/2 of second test:

Product: Cosmetic Talc

Total material ran: 88 tons

Total time for run: 13.5 hours

Hourly rate: 6.51 tons/hr

154

Third test, and 1/2 of second test:

Product: 7 micron talc

Total material ran: 48 tons

Total time for run: 10 hours

Hourly rate: 4.8 tons/hr

If you have any question, please don't hesitate to call me. Regards,

Hector Diaz-Stringel

August 22, 2001

Mr. Todd Brozell  
Air Control Techniques, P.C.  
301 East Durham Road  
Cary, NC 27513

Dear Todd,

The following are the production rates for the equipment you tested last week.

August 14

Limestone Storage Bin  
Flexkleen fabric filter dust collector

This bin received fine ground (3.5 microns) limestone product at an average rate of 1.96 tons per hour during the test.

August 15

Two Classifiers (Identical Units)  
Torit cartridge dust collector

The two classifiers processed an average rate of 1.8 tons per hour of product with average size range of 5 to 7 microns.

August 16

Roller Mill (Raymond Mill)  
Mikropul fabric filter dust collector

This mill produced on average rate of 6.3 tons per hour of product with an average size of 75 microns until 9:45AM. After 9:45AM, the mill produced an average rate of 14.0 tons per hour of product with an average size of 45 microns. There was no downtime for the product changeover; this change occurs instantaneously.

It was a pleasure working you and your crew. Please call me if you have any questions.

Sincerely,

Jeffrey C. Carlton, PE  
Environmental Manager

RE: J. M. Huber Corporation - Quincy, Illinois  
Stack Test Throughput Information

Dear Mr. Brozell:

The throughput information during the stack tests is as follows:

## Mill 7

| Run # | Run Time  | Throughput     | Date   |
|-------|-----------|----------------|--------|
| 1     | 0807-1037 | 3.75 tons/hour | 9/5/01 |
| 2     | 1049-1254 | 3.75 tons/hour | 9/5/01 |
| 3     | 1306-1508 | 3.75 tons/hour | 9/5/01 |

## Mill 17

| Run # | Run Time  | Throughput     | Date   |
|-------|-----------|----------------|--------|
| 1     | 0712-0928 | 0.50 tons/hour | 9/6/01 |
| 2     | 0935-1135 | 0.50 tons/hour | 9/6/01 |
| 3     | 1142-1351 | 0.50 tons/hour | 9/6/01 |

Should you have any questions regarding this matter, please do not hesitate to contact me  
at 217-224-8737, ext. 3353.

Sincerely,

Todd Brozell
