This report was prepared by Jerry Havens, Department Of Chemical Engineering, University Of Arkansas, Fayetteville, AR 72701, under subcontract to PEI Associates, Cincinnati, OH 45246, in partial fulfillment of PEI's efforts under EPA Contract No. 68-02-4351. The EPA Project Officer for this report was Dave Guinnup, U. S. EPA (MD 14), Research Triangle Park, NC 27711. The report and computer code are being made available through the National Technical Information Service (NTIS), 5285 Port Royal Road, Springfield, VA 22161.

PREFACE

Version 2.1 of the elevated dense gas dispersion model, DEGADIS, has been developed by Dr. Jerry Havens and Dr. Tom Spicer of the University of Arkansas with the support of funding from the United States Environmental Protection Agency (EPA). While this model has not been extensively tested against field data and is subject to specific limitations and uncertainties, the EPA is making it publicly available through the National Technical Information Service (NTIS) as a research tool pending further model evaluation and development.

As developed, the DEGADIS 2.1 model is intended to completely replace the previous version of the model, DEGADIS 2.0. Version 2.1 incorporates a newly developed jet-plume model which will result in a plume which disperses in a fashion consistent with current Gaussian plume models if the plume becomes neutrally buoyant before it is predicted to fall to the ground. This represents a substantial improvement over the previous version and extends the applicability of the model into the not-denser-than-air regime. Specifically, the new jet-plume model provides for:

(a) automatic adjustment of integration step size using the Runge-Kutta-Gill method;
(b) elliptical plume cross-section with air entrainment specified consistent with the Pasquill-Gifford plume dispersion coefficient representation of atmospheric turbulent entrainment;
(c) user specification of averaging time;
(d) ground reflection of the plume when its lower boundary reaches ground level; and
(e) application to scenarios where the plume remains aloft.

A technical description of the new jet-plume model is found in Section III of this User's Guide.

Source code for the model is provided in archived form with a dearchiving program. The code may be dearchived on an IBM-compatible PC using the instructions listed in the file named "README.NOW". The dearchived source code files should then be transferred to a VAX computer. At this point several files must then be renamed prior to compilation and execution. Specific information on the renaming process is contained in the file AAREADME.TXT. Print this file and the compilation batch file, BUILD.COM, prior to attempting compilation.

It is the concern of the EPA that this model be applied only within the framework of its intended use. To this end the user is referred to the specific recommendations in Section VI for model application. In addition the EPA is in the process of preparing a general guidance document to assist the typical regulatory user in the execution of denser-than-air cloud dispersion models.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

LIST OF FIGURES (continued)

LIST OF SYMBOLS

a_e	empirical coefficient in Equation (III.2)
a_v	empirical constant (1.3) in Equations (V.6) and (V.27)
B_{EFF}	effective width of gas plume (m)
B_i'	local half width of source seen by observer i (m)
b	half width of horizontally homogeneous central section of gas plume (m)
b_e	empirical power in Equation (III.2)
b_j	characteristic jet width (m)
b_v	empirical constant (1.2) in Equations (V.8) and (V.28)
C_E	constant (1.15) in density intrusion (spreading) relation
C_p	heat capacity (J/kg K)
C_{p_a}	heat capacity of air (J/kg K)
C_{p_c}	heat capacity of contaminant (J/kg K)
C_{p_w}	heat capacity of water (liquid phase) (J/kg K)
c	local concentration (kg/m^3)
c_c	centerline concentration (kg/m^3)
$c_{c,L}$	vertically averaged layer concentration (kg/m^3)
c_f	friction coefficient
c_c'	centerline, ground-level concentration corrected for x-direction dispersion (kg/m^3)
D	source diameter (m)
D_h	added enthalpy (J/kg)
D'	diffusivity (m^2/s)
d_v	empirical constant (0.64) in Equations (V.4) and (V.12)
E	plume strength (kg/s)

$E(t)$	contaminant primary source rate (kg contaminant/s)
E_1	air entrainment associated with a free turbulent jet (kg/ms)
E_2	air entrainment associated with a bending plume (kg/ms)
E_3	jet/plume air entrainment associated with passive atmospheric dispersion (kg/ms)
$E_{3,a}$	air entrainment associated with passive atmospheric dispersion (kg/ms)
e_v	empirical constant (20.) in Equations (V.5) and (V.15)
F	overall mass transfer coefficient (kg/m^2 s)
F_f	mass transfer coefficient due to forced convection (kg/m^2 s)
F_n	mass transfer coefficient due to natural convection (kg/m^2 s)
Fr	Froude number, $\rho_a u_a^2/(g(\rho_e - \rho_a)D)$
Fr_h	"horizontal" Froude number, $u_a/[gD(\rho_e - \rho_a)/\rho_a]^{1/2}$
Fr_r	"release" Froude number, $V/[gD(\rho_e - \rho_a)/\rho_a]^{1/2}$
Gr	Grashoff number
g	acceleration of gravity (m/s^2)
H	characteristic release depth or depth of density intrusion or cloud (m)
H_a	ambient absolute humidity (kg water/kg dry air)
H_{EFF}	effective cloud depth (m)
H_h	height of head in density-driven flow (m)
H_L	total layer depth (m)
H_r	maximum plume rise above stack (m)
H_s	stack (exit) height (m)
H_t	height of tail in density-driven flow (m)
H_1	average depth of gravity current head (m)
H_4	depth of inward internal flow in a gravity current head (m)

h enthalpy of source blanket (J/kg)

h_a enthalpy of ambient humid air (J/kg)

h_E enthalpy associated with primary source mass rate (J/kg)

h_f heat transfer coefficient due to forced convection (J/m^2 s K)

h_L enthalpy of vertically averaged layer (J/kg)

h_n heat transfer coefficient due to natural convection (J/m^2 s K)

h_0 overall heat transfer coefficient (J/m^2 s K)

h_p enthalpy of primary source (J/kg)

h_w enthalpy associated with mass flux of water from surface (J/kg)

J release momentum ratio

K_0 constant in Equation (V.96) ($m^{1-\gamma_1}$)

K_y horizontal turbulent diffusivity (m^2/s)

K_z vertical turbulent diffusivity (m^2/s)

k von Karman's constant, 0.35

k_1 - k_6 constants defined by Equations (III.14)-(III.19)

L source length (m)

L_B buoyancy length scale (m)

M total cloud mass (kg)

M_a total mass of air in the cloud (kg)

M_c total mass of contaminant in the cloud (kg)

M_i initial cloud mass (kg)

MW molecular weight

$\dot{M}_a$ mass rate of air entrainment into the cloud (kg/s)

$\dot{M}_{w,s}$ mass rate of water transfer to the cloud from the water surface under the source (kg/s)

N	number of observers
Nu	Nusselt number
P	cloud momentum (kg m/s)
P_e	perimeter of R' (m)
P_h	momentum of head in density-driven flow (kg m/s)
P_t	momentum of tail in density-driven flow (kg m/s)
P_v	virtual momentum due to acceleration reaction (kg m/s)
Pr	Prandtl number
p	atmospheric pressure (atm)
$p_{w,c}$	partial pressure of water in the cloud (atm)
$p^*_{w,s}$	vapor pressure of water at the surface temperature (atm)
Q	volumetric release rate (m^3/s)
Q_E	source mass flux (kg/m^2 s)
Q_e	volumetric entrainment flux (m/s)
Q_l	flux of ambient fluid into front of gravity current head (m/s)
$\dot{Q}_s$	rate of heat transfer from the surface (J/s)
Q_*	atmospheric takeup flux (kg/m^2 s)
Q_{*max}	maximum potential atmospheric takeup flux of contaminant (kg/m^2 s)
q_s	surface heat flux (J/m^2 s)
R	gas source radius (m)
R_h	inner radius of head in density-driven flow (m)
R_m	value of R when ($\pi R^2 Q_*$) is a maximum (m)
R_{max}	maximum radius of the cloud (m)
R_p	primary source radius (m)
R'	jet/plume region perpendicular to the axis

Ri_c	release Richardson number
Ri_f	Richardson number associated with the front velocity, Equation (V.11)
Ri_T	Richardson number associated with temperature differences, Equation (V.88)
Ri'_*	Richardson number associated with density differences corrected for convective scale velocity
Ri_*	Richardson number associated with density differences, Equation (V.78)
r	radial distance to jet/plume axis (m)
S	length of zone of flow establishment (m)
Sc	Schmidt number
Sh	Sherwood number
St_H	Stanton number for heat transfer
St_M	Stanton number for mass transfer
S_y	horizontal concentration scaling parameter (m)
S_z	vertical concentration scaling parameter (m)
S_{z0}	S_z at the downwind edge of the source (x = L/2) (m)
S_{z0_m}	value of S_{z0} when $(\pi R^2 Q_*)$ is a maximum (m)
s	distance along plume axis (m)
T	temperature associated with source blanket enthalpy (K)
$T_{c,L}$	temperature associated with layer-averaged enthalpy (K)
T_s	surface temperature (K)
t	time (s)
t_a	averaging time (s)
$t_{a,i}$	"instantaneous" averaging time associated with puff dispersion coefficients
t_p	averaging time associated with peak measured concentrations (s)

t_s specified time (s)

t_{dn_i} time when observer i encounters downwind edge (s)

t_{up_i} time when observer i encounters upwind edge (s)

u ambient (wind) velocity (m/s)

u_a ambient average velocity (m/s)

u_c jet/plume excess velocity at axis (m)

u_e horizontal or frontal entrainment velocity (m/s)

u_{EFF} effective cloud advection velocity (m/s)

u_f cloud front velocity (m/s)

u_i velocity of observer i (m/s)

u_L average transport velocity associated with H_L (m/s)

u_x wind velocity, along x-direction (m/s)

u_0 wind velocity measured at $z = z_0$ (m/s)

u_3 internal flow out of gravity current head (m/s)

u_4 internal flow into gravity current head (m/s)

u_* friction velocity (m/s)

$\bar{u}$ characteristic average velocity (m/s)

V jet velocity (m/s)

V_H heat transfer velocity (0.0125 m/s) in Equation (V.38) (m/s)

w_a mass fraction of air

w_c mass fraction of contaminant

$w_{c,p}$ mass fraction of contaminant in primary source

w_e vertical entrainment velocity associated with H_L (m/s)

w_* convective scale velocity (m/s)

w'_e entrainment velocity associated with H_{EFF} (m/s)

x_c downwind distance to centerline ground contact (m)

$x_i(t)$	x position of observer i at time t (m)
x_{pi}	position of puff center due to observer i (m)
x_t	downwind distance where gravity spreading terminates (m)
x_v	virtual point source distance (m)
x_{dn_i}	x position of downwind edge of source for observer i
x_{up_i}	x position of upwind edge of source for observer i
$\bar{x}$	downwind distance to maximum rise (m)
x,y,z	Cartesian coordinates (m)
x_0	downwind edge of the gas source (m)
y'	local lateral dimension (m)
z_j	elevation of jet/plume centerline (m)
z_R	surface roughness (m)
z_0	reference height in wind velocity profile specification (m)
z'	local vertical dimension perpendicular to the jet/plume axis (m)
α	constant in power law wind profile
α_1	jet entrainment coefficient
α_2	line thermal entrainment coefficient
β_y	constant in σ_y correlation in Equation (V.97)
β_z	power in σ_z correlation
Γ	gamma function
γ	ratio of $(\rho - \rho_a)/c$
γ_1	constant in Equation (V.96)
γ_z	constant in σ_z correlation
Δ	ratio of $(\rho - \rho_a)/\rho$
ΔT	temperature driving force (K) $(T_s - T_{c,L})$ or $(T_s - T)$

Δ' ratio of $(\rho - \rho_a)/\rho_a$

δ empirical constant (2.15)

δ_L empirical constant (2.15) in Equation (V.53)

δ_v constant (0.20) in Equation (V.25)

δ_y constant in σ_y correlation in Equation (V.97)

δ_z constant in σ_z correlation

ϵ frontal entrainment coefficient (0.59) in Equation (V.33)

ς collection of terms defined by Equation (V.62) ($m^{-1/(1+\alpha)}$)

λ Monin-Obukhov length (m)

μ viscosity (kg/m s)

ρ density of gas-air mixture (kg/m^3)

ρ_a air density (kg/m^3)

ρ_c jet/plume excess density at axis (kg/m^3)

ρ_e density of released gas (kg/m^3)

ρ_L vertically averaged layer density (kg/m^3)

ρ_0 density of contaminant's saturated vapor at T_0 (kg/m^3)

θ angle between plume axis and horizontal (radians)

λ^2 turbulent Schmidt number, 1.42

σ_r concentration profile parameter for an axisymmetrical jet/plume (m)

$\sigma_{x,a}$ Pasquill-Gifford x-direction (ambient) dispersion coefficient (m)

$\sigma_{y,a}$ Pasquill-Gifford y-direction (ambient) dispersion coefficient (m)

$\sigma_{y'}$ concentration profile parameter in the y' direction (m)

$\sigma_{z,a}$ Pasquill-Gifford z-direction (ambient) dispersion coefficient (m)

$\sigma_{z'}$ concentration profile parameter in the z' direction (m)

σ_1^2 variance associated with E_1 (m^2)

σ_2^2 variance associated with E_2 (m^2)

ϕ	function describing influence of stable density stratification on vertical diffusion, Equation (V.76)
$\hat{\phi}$	integrated source entrainment function
Ψ	logarithmic velocity profile correction function
χ_c	jet centerline concentration at centerline touchdown

I. INTRODUCTION

Episodic releases of hazardous chemical gases from chemical process pressure relief operations can pose significant hazards to public health. Conventional air pollutant dispersion models may not be applicable for assessing the consequences of such releases, particularly when the gases released are denser than air. The DEGADIS model (Havens and Spicer, 1985) was designed to model the atmospheric dispersion of ground-level, area-source dense gas (or aerosol) clouds released with zero (initial) momentum into an atmospheric boundary layer over flat, level terrain. DEGADIS describes the dispersion processes which accompany the ensuing gravity-driven flow and entrainment of the gas into the atmospheric boundary layer, and it has been verified by comparison with a wide range of laboratory and field-scale heavy gas release/dispersion data. However, DEGADIS made no provision for processes which occur in high velocity releases, as from pressure relief valves.

Ooms, Mahieu, and Zelis (1974) reported a mathematical model for estimating the trajectory and dilution of dense gas jet plumes. The model comprised simplified balance equations for mass, momentum, and energy, with Gaussian similarity profiles for velocity, density, and concentration in the jet. Havens (1988) interfaced Ooms' jet-plume model with DEGADIS to provide for prediction of the trajectory and dilution of an elevated dense gas jet to ground contact, with (DEGADIS) prediction of the ensuing ground-level plume dispersion.

The purpose of this work was to improve the jet-plume/DEGADIS model as follows:

- The jet-plume part of the model was modified to provide for elliptical plume shape (cross-section) with air entrainment specified to be consistent with the Pasquill-Gifford plume dispersion coefficient representation of atmospheric turbulent entrainment. This modification allows application of the model to scenarios where the plume remains aloft.

- The jet-plume part of the model was modified to incorporate ground reflection when the plume (lower) boundary reaches ground level.

- The jet-plume part of the model was modified to provide for automatic adjustment of integration step-size (using the Runge-Kutta-Gill method as in DEGADIS). This modification improves the computational efficiency of the model.

II. CHARACTERIZING GAS DENSITY EFFECTS ON ATMOSPHERIC DISPERSION

Atmospheric dispersion of gas releases may involve the following fluid flow regimes:

jet • buoyancy-dominated • stably-stratified • passive dispersion

All four regimes, which may be present in different degrees depending on the rate and (characteristic) dimensions of the release, gas density, and characteristics of the atmospheric flow, should be accounted for in a general application dispersion model. The dispersion (and trajectory) of vertical jets (perpendicular to the wind flow) can be modeled with the jet-plume model described here, and the buoyancy-dominated, stably-stratified, and passive dispersion regimes (on level, unobstructed terrain) can be modeled with DEGADIS (Havens and Spicer, 1985).

The jet-plume model currently does not provide for simulation of horizontal jets (such as might occur from ruptured gas transfer lines). Consequently, we consider here other methods for estimating the relative importance of the four dispersion regimes for ground level releases with horizontal momentum. In rapid releases of large quantities of dense gas (with low initial momentum) a cloud having similar vertical and horizontal dimensions may form. In this "buoyancy-dominated regime", (gravity-induced) slumping and lateral spreading motion ensues until the kinetic energy of the buoyancy-driven flow is dissipated. The gravity-induced flow, which may effect mixing (primarily at the advancing vapor cloud front), can be an important determinant of the shape and extent of the gas cloud. After the kinetic energy of the buoyancy-driven flow is dissipated, the dispersion process following can be described as a "stably stratified" plume (or cloud) embedded in the mean wind flow. The density stratification present in this regime, which can be much stronger than that occurring naturally in the atmospheric boundary layer, tends to damp turbulence and reduce vertical mixing. As the dispersion proceeds, the stable stratification due to the dense gas decreases until the dispersion process can be represented as a neutrally buoyant plume (or cloud) in the mean wind flow. This (final) dispersion regime can be predicted with passive contaminant dispersion theory.

Havens and Spicer (1985) suggested criteria (based on water tunnel experiments reported by Britter (1980)) for determining the importance of each of the low-momentum flow regimes described above. In Britter's experiments brine was released (at floor level) into a water tunnel flow, and the lateral and upwind extent of the brine/water plume was measured as a function of the buoyancy length scale

$$L_B = Qg(\rho e - \rho_a)/(\rho_e u^3)$$

where Q was the volumetric (brine) emission rate and u was the water-tunnel flow velocity. Britter's data indicated releases were passive

from the source when $L_B/D \lesssim 0.005$ and were dominated by the negative buoyancy dispersion regime when $L_B/D \gtrsim 0.1$. The following Release Richardson number criteria, based on these observations, were suggested:

If $Ri_C \gtrsim 30$	negative buoyancy-dominated	
If $1 \lesssim Ri_c \lesssim 30$	stably stratified shear flow	
If $Ri_c \lesssim 1$	passive dispersion	(II.1)

where $Ri_c = g(\rho_e - \rho_a)H/(\rho_a u_*)$. The reported values reflect the ratio $(u/u_*) = 16$ for Britter's water-tunnel flow, and the length scale corresponding to the depth of the layer was approximated by $H = Q/uD$.

High (initial) momentum releases require additional consideration if jet entrainment dominates other air entrainment mechanisms. In the negative buoyancy-dominated regime, the ambient flow does not strongly affect the rate of air entrainment. Consequently, the relative importance of buoyancy-driven and (horizontal, near-ground-level) jet flow effects can be evaluated using the criterion based on Britter's data (with the release velocity V used in place of the ambient velocity in the buoyancy length scale). Jet entrainment dominates the negative buoyancy regime entrainment when

$$\left[\frac{V}{u_*}\right]^2 \gtrsim 10\ Ri_c \qquad \text{(II.2)}$$

This criterion suggests that dominance of jet effects decreases with increased jet density (since buoyancy-driven flow frontal air entrainment increases).

The air entrainment into a turbulent free jet can be estimated as (Wheatley, 1986):

$$\frac{dM_a}{dx} = \left[\frac{0.159}{2}\right]\left[\frac{2\pi R}{2}\right] V\ \rho_a \qquad \text{(II.3)}$$

The rate of (vertical) air entrainment (per unit width) for the stably-stratified shear flow and passive dispersion regimes predicted by DEGADIS is

$$\frac{d}{dx}\left(\rho_L u_L H_L\right) = \frac{\rho_a \delta_L k u_* (1 + \alpha)}{\phi(Ri_*)} \qquad \text{(II.4)}$$

where $\phi(Ri_*) \cong 0.88 + 0.099\ Ri_*$. Using an effective width of $2\pi R$, a typical value of $\alpha = 0.2$, $\delta_L = 2.1$, $k = 0.35$, and $(u/u_*) = 30$ (typical of atmospheric boundary layers), the above equations can be combined to show that jet entrainment dominates the stably-stratified flow regime entrainment when

$$\frac{V}{u} \gtrsim 16/(19 + Ri_c) \qquad \text{(II.5)}$$

This criterion suggests that dominance of jet effects increases with increased jet density (since stably-stratified flow entrainment decreases). Further, when $Ri_c \lesssim 1$ the criterion suggests that jet effects dominate the passive dispersion regime when $(V/u) \gtrsim 0.8$, which is consistent with the criterion suggested by Cude (1974) and Wheatley (1986).

Summarizing, the following procedure can be used to determine the (starting) dominant dispersion regime:

(1) Calculate $Ri_c = g(\rho_e - \rho_a)H/(\rho_a u_*^2)$.

(2) Determine the dominant (nonjet) dispersion regime using Equation (II.1).

(3) Determine if horizontal jet effects dominate the regime determined in (2), using the relationships summarized in Table II.1.

Table II.1. Criteria for Determining Dominance of Jet Effects for Ground-Level Releases

Ground-level jet effects dominate:	
• negative buoyancy-dominated regimes when	$\left[\frac{V}{u_*}\right]^2 \gtrsim 10\ Ri_c$,
• stably stratified shear flow regimes when	$V/u \gtrsim 16/(19 + Ri_c)$, and
• passive dispersion regimes when	$V/u \gtrsim 0.8$

III. DESCRIPTION OF THE JET-PLUME MODEL

Gas (or aerosol) jet releases, such as might occur in chemical process pressure relief operations, are modeled as vertically directed releases of pure material into the atmospheric flow field. The jet is assumed to be discharged from a circular vent with a (constant) uniform velocity profile. At some distance downwind of the release, the velocity and concentration profiles are assumed Gaussian.

Zone of Flow Establishment

The region before Gaussian similarity velocity and concentration profiles are established is the so-called zone of flow establishment. Pratte and Baines (1967) reported that the length of the potential core (S_o) of a jet released from a tube perpendicular to a cross flow approaches the potential core length for a turbulent free jet with no cross flow as the ratio of the jet velocity to the cross-flow velocity (V/u_a) becomes large. Although S_o is also a function of the Reynolds number (in the tube), Reynolds number dependence is less important for large release momentum. Pratte and Baines' (largest Reynolds number) data were correlated here as

$$(S_o/D) = 6.4\ (1 - \exp(-0.48(V/u_a))) \qquad \text{(III-1)}$$

where D is the diameter of the release. The form of Equation (III-1) was chosen so that (S_o/D) approaches 0 as (V/u_a) approaches 0 and (S_o/D) approaches 6.4 as (V/u_a) becomes large. Chassaing et al. (1974) point out that similarity profiles are not established until some distance after the potential core has vanished. Consequently, the length of the zone of flow establishment (S) is modeled as

$$(S/D) = 7.7 \left\{ 1 - \exp\left[-0.48 \frac{\rho_e V}{\rho_a u_a} \right] \right\} \qquad \text{(III.2)}$$

where (V/u_a) has been replaced with $(\rho_e V/\rho_a u_a)$ to allow extended application for non-ambient-density gases.

Kamotani and Greber (1972) parameterized the trajectory of the jet-plume velocity profile in the zone of flow establishment as

$$x/D = a_e\ (z/D)^{b_e} \qquad \text{(III.3)}$$

where a_e and b_e are empirical constants determined as a function of the momentum ratio of the release ($J = \rho_e V^2/(\rho_a u_a^2)$). Astleford et al. (1983) determined equations for a_e and b_e as functions of J from Kamotani and Greber's data. Morrow (1985) revised the equations to extend the range for smaller values of J and to include the effect of a release Froude number ($Fr = \rho_a u_a^2/(g(\rho_e-\rho_a)D)$); these equations are shown in Table III.1. Correlations were also determined here for a_e and

b_e for $50 < J < 600$ from Kamotani and Greber's original work, based on a least squares fit; these equations are also assumed to apply for $J > 600$.

Table III.1. Equations for a_e and b_e.

Momentum Ratio (J) Range	Froude Number (Fr) Range	a_e	b_e	Ref.
$J \leq 0.036$	all	$18.519\ J$	0.4	1
$0.036 < J \leq 10$	$Fr > 1.688$ or $Fr \leq 0$	$\exp[0.405465+0.24386 \ln J]$	0.4	1
	$0 < Fr \leq 1.688$	$\exp[0.2476+0.3016 \ln Fr +0.24386 \ln J)]$	0.4	1
$10 < J \leq 50$	all	$\exp[0.405465+0.131386 \ln J +0.054931 (\ln J)^2]$	$\exp[-0.744691 -0.074525 \ln J]$	2
$50 < J \leq 600$	all	$\exp[-2.58012+1.49202 \ln J -0.097623 (\ln J)^2]$	$\exp[-0.446718 -0.1950694 \ln J]$	3

At the end of the zone of flow establishment, the maximum jet-plume velocity is (approximately) the release velocity (V), and the centerline concentration is (approximately) the pure contaminant concentration. The jet angle (with the horizontal) is determined by x, z, and S from Equations (III.2) and (III.3).

Zone of Established Flow

For the zone of established flow, Ooms (1972) assumed Gaussian similarity profiles (single length scale) for velocity, density, and concentration. The concentration profile was

$$c(r,s) = c_c(s) \exp\left\{ - \left[\frac{r}{\lambda\, b_j(s)} \right]^2 \right\} \qquad \text{(III.4)}$$

where c_c represents the centerline concentration and λ^2 is a turbulent Schmidt number which represents the square of the ratio of the characteristic length of the concentration profile to the characteristic length of the velocity profile (b_j). By contrast, the Pasquill-Gifford representation of atmospheric turbulent dispersion assumes the following Gaussian profile:

$$c(x,y,z) = c_c(x) \exp\left\{ - \frac{1}{2}\left[\frac{y}{\sigma_y(x)} \right]^2 - \frac{1}{2}\left[\frac{z}{\sigma_z(x)} \right]^2 \right\} \qquad \text{(III.5)}$$

For a symmetric plume, $\sigma_y = \sigma_z$ ($=\sigma_r$), and $r^2 = y^2 + z^2$; Equation (III.5) becomes

$$c(x,r) = c_c(x) \exp\left\{ - \frac{1}{2}\left[\frac{r}{\sigma_r(x)} \right]^2 \right\}, \qquad \text{(III.6)}$$

and the profile,

$$c(s,y',z') = c_c(s) \exp\left\{ - \frac{1}{2}\left[\frac{y'}{\sigma_{y'}(s)} \right]^2 - \frac{1}{2}\left[\frac{z'}{\sigma_{z'}(s)} \right]^2 \right\} \qquad \text{(III.7)}$$

where y' and z' denote the local lateral and vertical dimensions in the jet-plume (Figure III.1), incorporates Equations (III.4) and (III.5) and provides for a circular cross section initially ($\sigma_{y'} = \sigma_{z'}$) with transition to an elliptical cross section.

Associated profiles for velocity and density are also assumed:

$$u(s,y',z') = u_a \cos\theta + u_c(s) \exp\left\{ - \frac{1}{2}\left[\frac{\lambda\, y'}{\sigma_{y'}(s)} \right]^2 - \frac{1}{2}\left[\frac{\lambda\, z'}{\sigma_{z'}(s)} \right]^2 \right\} \qquad \text{(III.8)}$$

$$\rho(s,y',z') = \rho_a + \rho_c(s) \exp\left\{ - \frac{1}{2}\left[\frac{y'}{\sigma_{y'}(s)} \right]^2 - \frac{1}{2}\left[\frac{z'}{\sigma_{z'}(s)} \right]^2 \right\} \qquad \text{(III.9)}$$

Note that the turbulent Schmidt number now appears in the velocity profile. $\sigma_{y'}$ and $\sigma_{z'}$ should approach $\sigma_{y,a}$ and $\sigma_{z,a}$ for passive atmospheric

dispersion as the density and momentum of the jet/plume approach ambient values.

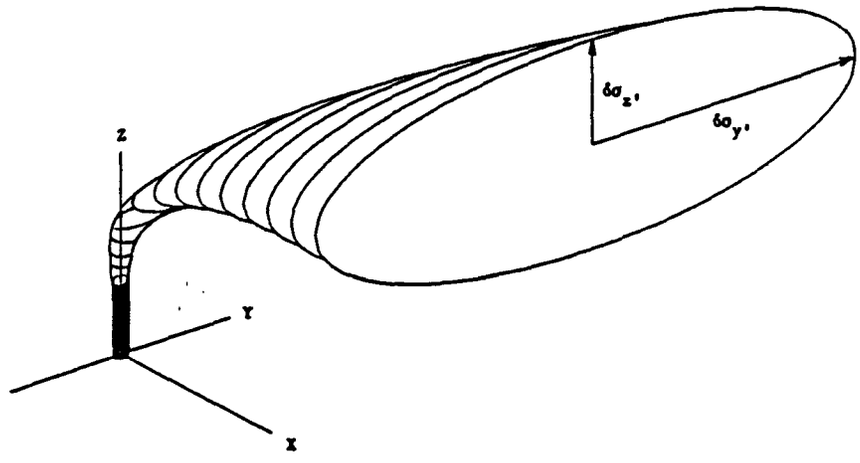

Figure III.1. Sketch of a Developing Jet in a Cross Flow.

The fundamental balance equations are:

Contaminant Mass Balance

$$\frac{d}{ds}\int_{R'} cu\ dR' = 0 \qquad \text{(III.10)}$$

Total Mass Balance

$$\frac{d}{ds}\int_{R'} \rho u\ dR' = E_1 + E_2 + E_3 \qquad \text{(III.11)}$$

X-Direction Momentum Balance

$$\frac{d}{ds}\int_{R'} \rho u\ (u\cos\theta)\ dR' = u_a(E_1 + E_2 + E_3) + c_d P_e \rho_a u_a^2 |\sin^3\theta|/2 \qquad \text{(III.12)}$$

Z-Direction Momentum Balance

$$\frac{d}{ds}\int_{R'} \rho u\ (u\sin\theta)\ dR' = \int_{R'} g(\rho_a - \rho)\ dR' - \text{sign}(\theta)\ c_d P_e \rho_a u_a^2 \sin^2\theta\ \cos\theta/2 \qquad \text{(III.13)}$$

The jet/plume boundary is assumed located where the concentration is one-tenth of the centerline value and encloses the region R'. (R' is an

ellipse or circle with major axes $\delta\sigma_{y'}$ and $\delta\sigma_{z'}$ where δ is a constant equal to 2.15; P_e is the perimeter of R'.) The term $(E_1 + E_2 + E_3)$ represents air entrainment into the jet plume by the three (independent) mechanisms discussed below. A drag force term assumed to act at right angles to the jet-plume trajectory is included on the right hand sides of Equations (III.12) and (III.13). The value used for c_d is 0.2; although this value of c_d is different from the value used by Ooms (1972) (since different length scales were used), its use in Equations (III.12) and (III.13) provides drag forces consistent with Ooms' predictions.

A (thermal) energy balance is not included in the balance equations given above. In the original formulation and in later work (Ooms, Mahieu, and Zelis, 1974), the energy balance was used to determine the developing jet temperature. However, since no provision was made for thermal energy transfer between the jet and its surroundings (e.g., the ground), the contaminant was (implicitly) assumed to mix adiabatically with ambient air, and an energy balance is not required if the adiabatic mixing properties are calculated beforehand.

For adiabatic mixing of two ideal gases with equal constant molal heat capacities, the ratio $\gamma = (\rho - \rho_a)/c$ is constant. Assumption of the density profile in Equation (III.9) and the concentration profile in Equation (III.7) is equivalent to assuming γ constant at any given distance, s. In the model development, $d\gamma/ds$ was assumed to be negligible. In the model implementation, γ is updated with distance based on the adiabatic mixing properties.

In Equations (III.10) - (III.13), u_a is considered constant for evaluation of the integrals. The value of u_a used is the averaged velocity over the top half of the jet plume, and u_a is updated with distance.

The integrals on the left-hand sides of Equations (III.10) - (III.13) do not have closed form solutions when R' represents an ellipse. If R' is approximated by a rectangle with an area equal to that of the original ellipse, the integrations are readily performed. (The approximating rectangle has sides with length $\sqrt{\pi}\delta\sigma_{y'}$ and $\sqrt{\pi}\delta\sigma_{z'}$.) The constants in Ooms' original formulation were compared to constants determined by approximating the circular cross section as square; the difference was less than 2%.

With the approximations stated above, six constants appear in the resulting equations:

$$k_1 = \frac{1}{\sigma_{y'}\sigma_{z'}} \int_{R'} \exp\left\{ -\frac{1}{2}\left[\left(\frac{y'}{\sigma_{y'}} \right)^2 + \left(\frac{z'}{\sigma_{z'}} \right)^2 \right] \right\} dR' \qquad \text{(III.14)}$$

$$k_2 = \frac{1}{\sigma_{y'}\sigma_{z'}} \int_{R'} \exp\left\{ -\frac{(1+\lambda^2)}{2} \left[\left(\frac{y'}{\sigma_{y'}} \right)^2 + \left(\frac{z'}{\sigma_{z'}} \right)^2 \right] \right\} dR' \qquad \text{(III.15)}$$

$$k_3 = \frac{1}{\sigma_{y'}\sigma_{z'}} \int_{R'} dR' = \pi \delta^2 \qquad \text{(III.16)}$$

$$k_4 = \frac{1}{\sigma_{y'}\sigma_{z'}} \int_{R'} \exp\left\{ -\frac{\lambda^2}{2} \left[\left(\frac{y'}{\sigma_{y'}} \right)^2 + \left(\frac{z'}{\sigma_{z'}} \right)^2 \right] \right\} dR' \qquad \text{(III.17)}$$

$$k_5 = \frac{1}{\sigma_{y'}\sigma_{z'}} \int_{R'} \exp\left\{ -\lambda^2 \left[\left(\frac{y'}{\sigma_{y'}} \right)^2 + \left(\frac{z'}{\sigma_{z'}} \right)^2 \right] \right\} dR' \qquad \text{(III.18)}$$

$$k_6 = \frac{1}{\sigma_{y'}\sigma_{z'}} \int_{R'} \exp\left\{ -\frac{(1+2\lambda^2)}{2} \left[\left(\frac{y'}{\sigma_{y'}} \right)^2 + \left(\frac{z'}{\sigma_{z'}} \right)^2 \right] \right\} dR' \qquad \text{(III.19)}$$

Air Entrainment

The balance equations for mass and x-direction momentum require specification of the air entrainment rate (E_1, E_2, and E_3 in Equations (III.11) and (III.13)).

E_1 represents the (near-field) air entrainment associated with jetting of the release. Although a cross flow is present, the momentum of the release dominates the ambient momentum when jetting is important, and the region near the jet release can be modeled as a free turbulent jet:

$$E_1 = \alpha_1 \rho_a P_e u_c \qquad \text{(III.20)}$$

where P_e is the perimeter of R′ and α_1 is the entrainment coefficient associated with this area. Note that E_1 is taken to be zero if $u_c < 0$. A value of $\alpha_1 = 0.028$ is based on a summary of free turbulent jet experiments reported by List (1982); although this value of α_1 is different from the value used by Ooms (1972) (since different length scales were used), its use in Equation (III.20) provides rates of air entrainment consistent with Ooms' predictions.

E_2 represents the air entrainment associated with a cross-flow velocity component perpendicular to the jet-plume centerline. In the absence of jetting, large scale vortices (which entrain air) will form

in a plume due to the cross flow. Richards (1963) measured the air entrainment rate into line thermals released in a calm environment. Based on Richards' experiments, E_2 is modeled as follows:

$$E_2 = \alpha_2 \rho_a P_e u_a |\sin\theta| \cos\theta \qquad \text{(III.21)}$$

where $u_a|\sin\theta|$ is the velocity component perpendicular to the jet-plume centerline and $\alpha_2 = 0.37$ is based on Richards' data. Ooms (1972) added the $\cos\theta$ term so that this contribution is present only in the far field. Again, although this value of α_2 is different from the value used by Ooms (1972), its use in Equation (III.21) provides rates of air entrainment consistent with Ooms' predictions.

E_3 represents the atmospheric air entrainment for a passive plume. For a passive plume, the atmospheric air entrainment rate ($E_{3,a}$) is given by

$$E_{3,a} = \frac{d}{dx} \int_{R'} \rho_a u_a \, dR' = \rho_a u_a \frac{d}{dx} \int_{R'} dR' = \rho_a u_a \frac{d}{dx} \left(k_3 \sigma_{y,a} \sigma_{z,a} \right)$$

(III-22)

where $\sigma_{y,a}$ and $\sigma_{z,a}$ denote the ambient lateral and vertical Pasquill-Gifford dispersion coefficients, respectively. Since k_3 is constant, Equation (III.22) becomes

$$E_{3,a} = k_3 \rho_a u_a \left(\sigma_{z,a} \frac{d\sigma_{y,a}}{dx} + \sigma_{y,a} \frac{d\sigma_{z,a}}{dx} \right) \qquad \text{(III.23)}$$

where the derivatives can be calculated from accepted correlations for $\sigma_{y,a}$ and $\sigma_{z,a}$, such as

$$\sigma_{y,a} = \delta_y x^{\beta_y} \qquad \text{(III.24)}$$

$$\sigma_{z,a} = \delta_z x^{\beta_z} \exp(\gamma_z (\ln(x))^2) \qquad \text{(III.25)}$$

(Seinfeld, 1986). Typical values for δ_z, β_z, and γ_z are given in Table III.2.

Methods recommended in Section V for determining the effect of averaging time are applied for the jet-plume model, and values for δ_y and β_y as a function of stability and averaging time are given in Equation (V.101). For the jet plume, E_3 is modeled as

$$E_3 = k_3 \rho_a u_a \left(\sigma_{z,a} \frac{d\sigma_{y,a}}{dx} + \sigma_{z,a} \frac{d\sigma_{y,a}}{dx} \right) \cos\theta \qquad \text{(III.26)}$$

where the $\cos\theta$ term is included because E_3 is required as a function of s.

Table III.2. Constants for Determination of σ_z from Seinfeld (1986) after Turner (1970)

Stability Class	δ_z[1]	β_z	γ_z
A	107.7	-1.7172	0.2770
B	0.1355	0.8752	0.0136
C	0.09623	0.9477	-0.0020
D	0.04134	1.1737	-0.0316
E	0.02275	1.3010	-0.0450
F	0.01122	1.4024	-0.0540

[1]for use in $\sigma_z = \delta_z x^{\beta_z} \exp(\gamma_z (\ln(x))^2)$ where σ_z and x are in meters.

Gravitational Force

The gravitational force term in Equation (III.13) is given by

$$\int_{R'} g(\rho_a - \rho)\, dR' = g\gamma \int_{R'} c\, dR' = k_1 g \gamma c_c \sigma_{y'} \sigma_{z'} \qquad \text{(III.27)}$$

As discussed earlier, γ is assumed constant in the equation development but is updated with distance in the model implementation. Note that Equation (III.27) applies for $\rho \leq \rho_a$ as well as $\rho > \rho_a$.

Additional Constraints

Along with an equation of state (such as the ideal gas law or an adiabatic mixing relationship between concentration and density), balance Equations (III.10) - (III.13) provide five constraints on the six unknowns c_c, ρ_c (or γ), u_c, θ, $\sigma_{y'}$, and $\sigma_{z'}$. Therefore, an additional constraint is required to solve the equations. The momentum balances provide the information needed to determine θ and u_c. The contaminant mass balance provides the information to determine c_c. The total mass balance provides the information to determine the product $\sigma_{y'}\sigma_{z'}$, but the balance equations provide no guidance for the individual values of $\sigma_{y'}$ and $\sigma_{z'}$. (No additional constraint was needed in Ooms' model since a single length scale was used.) The last constraint is to

be specified so that the values of $\sigma_{y'}$ and $\sigma_{z'}$ are consistent with atmospheric processes.

The model treats three (assumed) independent mechanisms for air entrainment. For independent processes, the variances are additive:

$$\sigma_{y'}^2 = \sigma_1^2 + \sigma_2^2 + \sigma_{y,a}^2 \qquad \text{(III.28)}$$

$$\sigma_{z'}^2 = \sigma_1^2 + \sigma_2^2 + \sigma_{z,a}^2 \qquad \text{(III.29)}$$

where σ_1^2 and σ_2^2 represent the variances associated with entrainment processes E_1 and E_2, respectively. Combining Equations (III.28) and (III.29):

$$\sigma_{y'}^2 - \sigma_{z'}^2 = \sigma_{y,a}^2 - \sigma_{z,a}^2 \qquad \text{(III.30)}$$

Equation (III.30) acts as the final constraint on the system. In the near field, $\sigma_{y,a}^2 - \sigma_{z,a}^2$ is small and $\sigma_{y'} \simeq \sigma_{z'}$. In the far field, $\sigma_{y'}$ and $\sigma_{z'}$ will approach $\sigma_{y,a}$ and $\sigma_{z,a}$, respectively.

Closure

Initial conditions for the zone of established flow are determined from the zone of flow establishment; initial values of $\sigma_{y'}$ and $\sigma_{z'}$ are determined from the contaminant mass balance and the (known) release rate. With $\lambda^2 = 1.42$ (List, 1982), the assumed profiles, balance equations, and assumptions are combined to give a system of ordinary differential equations as follows:

$$\begin{vmatrix} A_{11} & A_{12} & A_{13} & A_{14} \\ A_{21} & A_{22} & A_{23} & A_{24} \\ A_{31} & A_{32} & A_{33} & A_{34} \\ A_{41} & A_{42} & A_{43} & A_{44} \end{vmatrix} \begin{vmatrix} \frac{dc_c}{ds} \\ \frac{d}{ds}(\sigma_{y'},\sigma_{z'}) \\ \frac{d\theta}{ds} \\ \frac{du_c}{ds} \end{vmatrix} = \begin{vmatrix} B_1 \\ B_2 \\ B_3 \\ B_4 \end{vmatrix}$$

where

(Contaminant Mass Balance)

$$A_{11} = (k_1 u_a \cos\theta + k_2 u_c)\ \sigma_{y'},\sigma_{z'}$$

$$A_{12} = (k_1 u_a \cos\theta + k_2 u_c)\ c_c$$

$$A_{13} = -k_1 u_a \sin\theta\ c_c \sigma_{y'} \sigma_{z'}$$

$$A_{14} = k_2 c_c \sigma_{y'} \sigma_{z'}$$

$$B_1 = 0$$

(Total Mass Balance)

$$A_{21} = 0$$

$$A_{22} = \rho_a (k_1 u_a \cos\theta + k_2 u_c)$$

$$A_{23} = -\rho_a k_3 u_a \sin\theta\ \sigma_{y'} \sigma_{z'}$$

$$A_{24} = \rho_a k_4 \sigma_{y'} \sigma_{z'}$$

$$B_2 = E_1 + E_2 + E_3$$

(z-Direction Momentum Balance)

$$A_{31} = (k_1 u_a^2 \cos^2\theta \sin\theta + 2k_2 u_a u_c \cos\theta \sin\theta + k_6 u_c^2 \sin\theta)\ \gamma \sigma_{y'} \alpha_{z'}$$

$$A_{32} = \rho_a (k_3 u_a^2 \cos^2\theta \sin\theta + 2k_4 u_a u_c \cos\theta \sin\theta + k_5 u_c^2 \sin\theta) + (k_1 u_a^2 \cos^2\theta \sin\theta + 2k_2 u_a u_c \cos\theta \sin\theta + k_6 u_c^2 \sin\theta)\ \gamma c_c$$

$$A_{33} = \rho_a(-2k_3u_a^2 \cos\theta \sin^2\theta + k_3u_a^2 \cos^3\theta$$
$$-2k_4u_au_c \sin^2\theta + 2k_4u_au_c \cos^2\theta$$
$$+ k_5u_c^2 \cos\theta)\ \sigma_y,\sigma_z,$$
$$+ (-2k_1u_a^2 \cos\theta \sin^2\theta + k_1u_a^2 \cos^3\theta$$
$$- 2k_2u_au_c \sin^2\theta + 2k_2u_au_c \cos^2\theta$$
$$+ k_6u_c^2 \cos\theta)\ \gamma c_c\sigma_y,\sigma_z,$$

$$A_{34} = \rho_a(2k_4u_a \cos\theta \sin\theta + 2k_5u_c \sin\theta)\ \sigma_y,\sigma_z,$$
$$+ (2k_2u_a \cos\theta \sin\theta + 2k_6u_c \sin\theta)\ c_c\sigma_y,\sigma_z,$$

$$B_3 = gk_1\gamma c_c\sigma_y,\sigma_z,$$

(x-Direction Momentum Balance)

$$A_{41} = (k_1u_a^2 \cos^3\theta + 2k_2u_au_c \cos^2\theta + k_6u_c^2 \cos\theta)\ \gamma\sigma_y,\sigma_z,$$

$$A_{42} = \rho_a(k_3u_a^2\cos^3\theta + 2k_4u_au_c \cos^2\theta + k_5u_c^2 \cos\theta)$$
$$+ (k_1u_a^2 \cos^3\theta + 2k_2u_au_c \cos^2\theta + k_6u_c^2 \cos\theta)\ \gamma c_c$$

$$A_{43} = \rho_a(-_3u_a^2 \cos^2\theta \sin\theta - 4k_4u_au_c \cos\theta \sin\theta$$
$$- k_5u_c^2 \sin\theta)\ \sigma_y,\sigma_z,$$
$$+ (-3k_1u_a^2 \cos^2\theta \sin\theta - 4k_2u_au_c \cos\theta \sin\theta$$
$$- k_6u_c^2 \sin\theta)\ \gamma c_c\sigma_y,\sigma_z,$$

$$A_{44} = \rho_a(2k_4u_a \cos^2\theta + 2k_5u_c \cos\theta)\ \sigma_y,\sigma_z,$$
$$+ (2k_2u_a \cos^2\theta + 2k_6u_c \cos\theta)\ \gamma c_c\sigma_y,\sigma_z,$$

$$B_4 = u_a(E_1 + E_2 + E_3)$$

and

$$k_1 = 2\pi \left[\text{erf} \left(\frac{\delta}{2} \left[\frac{\pi}{2} \right]^{\frac{1}{2}} \right) \right]^2$$

$$k_2 = \left[\frac{2\pi}{1 + \lambda^2} \right] \left[\text{erf} \left(\frac{\delta}{2} \left[\frac{\pi(1 + \lambda^2)}{2} \right]^{\frac{1}{2}} \right) \right]^2$$

$$k_3 = \pi\delta^2$$

$$k_4 = \frac{2\pi}{\lambda^2} \left[\text{erf} \left(\frac{\delta\lambda}{2} \left[\frac{\pi}{2} \right]^{\frac{1}{2}} \right) \right]^2$$

$$k_5 = \frac{\pi}{\lambda^2} \left[\text{erf} \left(\frac{\delta\lambda \sqrt{\pi}}{2} \right) \right]^2$$

$$k_6 = \left[\frac{2\pi}{1 + 2\lambda^2} \right] \left[\text{erf} \left(\frac{\delta}{2} \left[\frac{\pi(1 + 2\lambda^2)}{2} \right]^{\frac{1}{2}} \right) \right]^2$$

After c_c is determined from the system of equations above, the contribution from the reflected image is approximated by

$$c_c \exp \left\{ - \frac{1}{2} \left[\frac{2 z_j}{\sigma_{z'}} \right]^2 \right\} \qquad \text{(III.31)}$$

so that the reported concentration is

$$c_c'' = c_c \left\{ 1 + \exp \left\{ - \frac{1}{2} \left[\frac{2 z_j}{\sigma_{z'}} \right]^2 \right\} \right\} \qquad \text{(III.32)}$$

The reported mole fraction and density are calculated based on c_c''. Although the method of images is a common approach for accounting for ground interactions with the plume, application of the method of images to this problem may cause c_c'' to increase with downwind distance. Note that at the centerline touchdown, $c_c'' = 2c_c$.

For Ooms model predictions, DEGADIS is used to model the subsequent dispersion when the jet-plume reaches ground level ($z_j = 0$). The ground-level source input to DEGADIS is modeled as a circular area source with radius $\delta\sigma_{y'}$ and concentration equal to the centerline value from the Ooms model. Note that the downwind distance reported in DEGADIS includes the distance to touchdown calculated in the Ooms model. A description of the DEGADIS model is included in Section V.

IV. EVALUATION OF THE JET-PLUME MODEL

A series of simulations were made with the jet-plume model to:

- compare the model predictions with wind tunnel dense gas jet trajectory and dilution data
- characterize the sensitivity of the model to the specification of entrainment coefficients α_1 and α_2.

Table IV.1 shows the "typical" jet releases simulated.

Table IV.1. Specification of Gas Release Rates for Modeling.

Jet Diameter m	Jet Velocity m/s	Gas Release Rate kg/s
0.05 (~2 in)	30.6 (~100 ft/s)	0.24
0.2 (~8 in)	91.7 (~300 ft/s)	11.52
0.5 (~20 in)	213.9 (~700 ft/s)	168.0

Comparison with Wind Tunnel Test Data

Hoot, Meroney, and Peterka (1973) reported plume rise, downwind distance to plume centerline touchdown, and dilution at touchdown for wind tunnel jet releases of Freon-12/air mixtures. The ranges of experimental variables studied were:

gas specific gravity (air = 1)	1.1 - 4.6
gas exit diameter, cm	0.32 and 0.64
gas exit height, cm	7.6 and 15.2
gas exit velocity/wind velocity ratio	2.5 - 25
wind (tunnel) velocity, m/s	0.23 and 0.46

Correlations (of the wind tunnel data) were presented for plume rise, distance to plume touchdown, and plume centerline concentration at (centerline) ground contact, in a laminar crosswind:

Plume Rise

$$H_r = 1.32\ D\ [(V/u_a)(\rho_e/\rho_a)]^{1/3} Fr_r^{2/3} \qquad \text{(IV.1)}$$

Downwind Distance to Maximum Rise

$$\bar{X} = (D\ u_a/V)\ Fr_r^2 \qquad \text{(IV.2)}$$

Downwind Distance to Centerline Ground Contact

$$X_c = 0.56\ D\ \{(H_r/D)^3[(2 + H_s/H_r)^3 - 1]u_a/V)^{1/2}Fr_h + \bar{X} \qquad \text{(IV.3)}$$

Centerline Concentration at Ground Contact

$$\chi_c = \frac{6.0\ Q}{u_a(2H_r + H_s)^2} \qquad \text{(IV.4)}$$

where D = initial jet diameter (m)

Fr = "release" Froude number, $V/[g\ D\ (\rho_e-\rho_a)/\rho_\rho]^{1/2}$

Fr_h = "horizontal" Froude number, $u_a/[g\ D\ (\rho_e-\rho_a)/\rho_a]^{1/2}$

H_r = maximum height of plume rise above stack (m)

H_s = exit height (m)

Q = steady-state jet rate (kg/s)

u_a = wind velocity (m/s)

V = initial jet velocity (m/s)

X_c = downwind distance to ground contact (centerline) (m)

$\bar{X}$ = downwind distance to maximum rise (m)

ρ_a = ambient air density (kg/m^3)

ρ_e = initial jet density (kg/m^3)

χ_c = jet centerline concentration at centerline touchdown (kg/m^3)

Note that Equation (IV.4) is based on analysis by Briggs presented in Guinnup (1989).

Table IV.2 compares the jet-plume model predictions for plume rise, downwind distance to ground contact, and concentration at ground contact with the results of Hoot et al.'s wind-tunnel data correlations for the "low diameter/low velocity", "typical diameter/typical velocity", and "high diameter/high velocity" cases (Table IV.1) in 3 and 6 m/s winds. Based on a scaled release height of 10 m, a surface roughness of 2.2 mm was assumed with the 3 and 6 m/s velocities because the jet-plume model implementation assumes a logarithmic velocity profile. This assumption causes overprediction of the wind tunnel velocities by greater than 20% for scaled heights greater than ~40 m. Since the wind tunnel correlations were for jets in a laminar crosswind, the simulations shown in Table IV.2 were made with the entrainment due to atmospheric turbulence (E_3) set to zero.

Table IV.2. Comparison of Jet-Plume Model Prediction with Hoot et al.'s Wind Tunnel Data Correlation

Gas Jet Density: 4.0 kg/m^3 Gas Jet Elevation: 10 m

(Hoot et al. correlation / Jet-Plume model prediction)

Maximum Rise, m (3, 6 m/s)		Distance to Ground Contact, m (3, 6 m/s)		Centerline Concentration at Ground Contact kg/m^3 x 10^3 (3, 6 m/s)	
Low Diameter (0.05 m) - Low Velocity (30.6 m/s)					
3.0/2.6	2.4/1.7	150/160	375/370	1.9/4.2	1.1/2.6
Typical Diameter (0.2 m) - Typical Velocity (91.7 m/s)					
22.6/20.9	17.9/15.2	165/170	350/320	7.6/17.4	5.4/14.3
High Diameter (0.5 m) - High Velocity (213.9 m/s)					
97.0/87.4	76.9/66.5	320/380	650/680	8.1/18.3	6.3/15.5

The model predictions of maximum rise and distance to centerline ground contact are in good agreement with the wind tunnel correlations. The agreement between model predictions of distance to centerline ground contact and the wind tunnel correlations tends to degrade as the maximum rise increases because the logarithmic velocity profile assumed in the model overpredicts the (laminar) wind tunnel velocity. The model prediction of the maximum concentration at centerline ground contact differs by a factor of about two from the observed concentration. Note that if interaction with the ground were not included in the calculations, the predicted model concentrations would be reduced by exactly a factor of 2. Therefore, the agreement between model predictions of the maximum concentration at centerline ground contact and the wind tunnel correlations is considered good.

Sensitivity to Entrainment Coefficient Specification

The model sensitivity to the coefficients α_1 and α_2 was determined by systematic variation around the values given above. All simulations were of denser-than-air gas jets (initial density 4.0 kg/m^3) exiting vertically upward at 10 meters elevation. The predictions assumed a

logarithmic velocity profile with 3 and 6 m/s velocities at 10 m elevation, a surface roughness of 2.2 mm, and D stability. Table IV.3 shows the effect of individually varying the entrainment coefficients α_1 and α_2 by factors of two below and above the values given above, for the "low diameter/low velocity", "typical diameter/typical velocity", and "high diameter/high velocity" cases (Table IV.1) in 3 and 6 m/s winds.

The predictions of maximum rise and distance to centerline ground contact are relatively insensitive to factor-of-four variations in α_1 and α_2 over the range of release conditions in Table IV.1. The predictions of maximum concentration at centerline ground contact are more sensitive to variations in α_1 and α_2; factor-of-four variations in α_1 and α_2 resulted in concentration changes of less than a factor of ~2 when concentrations were compared at the same distances.

Table IV.3. Sensitivity of Jet-Plume Model Prediction to Variation of Entrainment Coefficients α_1 and α_2

Gas Jet Density: 4.0 kg/m^3 Gas Jet Elevation: 10 m

Entrainment Coefficients α_1	α_2	Maximum Rise, m (3, 6 m/s)		Distance to Ground Contact, m (3, 6 m/s)		Centerline Concentration at Ground Contact kg/m^3 x 10^3 (3, 6 m/s)

V. DESCRIPTION OF THE DEGADIS DENSE GAS DISPERSION MODEL

DEGADIS (DEnse GAs DISpersion) model development was sponsored by the U.S. Coast Guard and the Gas Research Institute (Havens and Spicer, 1985). DEGADIS is an adaptation of the Shell HEGADAS model (Colenbrander, 1980 and Colenbrander and Puttock, 1983) and incorporates some techniques proposed by van Ulden (1983). It is designed to model the atmospheric dispersion of ground-level, area-source dense gas (or aerosol) clouds released with zero (initial) momentum into an atmospheric boundary layer flow over flat, level terrain.

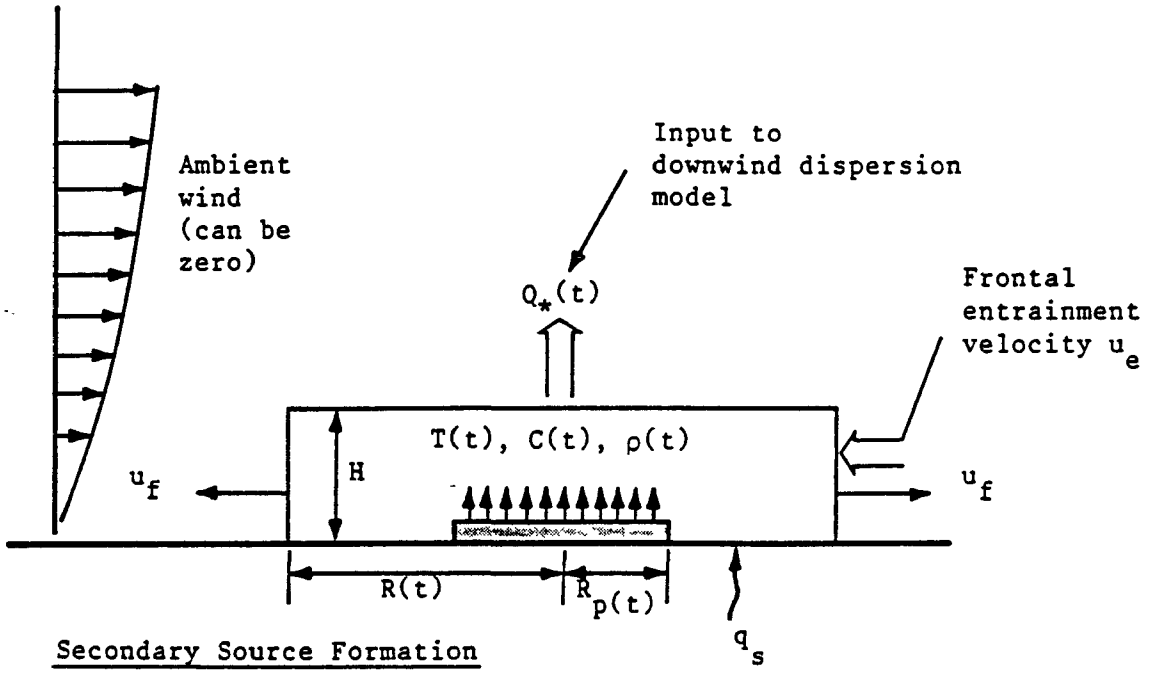
If a gas release rate does not exceed the potential atmospheric takeup rate, the gas is taken up directly by the atmospheric flow and dispersed downwind. If a gas release rate exceeds the potential atmospheric takeup rate, a denser-than-air "secondary source" blanket is formed over the primary source, and this near-field, buoyancy-dominated regime is modeled using a lumped parameter model (spatially averaged properties) which incorporates air entrainment at the gravity-spreading front using a frontal entrainment velocity (Figure V.1). Downwind dispersion is modeled with a power law concentration distribution in the vertical direction and a modified Gaussian profile in the horizontal direction with a power law specification for the wind profile. The downwind dispersion models the ensemble average of the gas concentrations.

Secondary Source Blanket Formation

A denser-than-air gas "secondary source" cloud or blanket may be formed over an evaporating liquid pool (or otherwise specified ground-level emission source) or by the instantaneous release of a volume of gas. A lumped parameter model of such a blanket is illustrated in Figure V.1. The blanket is represented as a cylindrical gas volume which spreads laterally as a density-driven flow with entrainment from the top of the source blanket by wind shear and air entrainment into the advancing front edge. The blanket spreads laterally until the atmospheric takeup rate from the top is matched by the air entrainment rate from the side and, if applicable, by the rate of gas addition from under the blanket. The blanket center is assumed stationary over the source.

Secondary Source Blanket Extent for Ground-Level Emission Sources

The downwind emission rate from the blanket is equal to the potential atmospheric takeup rate, Q^*_{max}. For $E(t)/\pi R_p^2(t) > Q^*_{max}$, a blanket is formed over the primary source. The blanket frontal (spreading) velocity is modeled as



$$C(x,y,z) = C_C(x) \exp\left[-\left(\frac{|y|-b(x)}{S_y(x)}\right)^2 - \left(\frac{z}{S_z(x)}\right)^{1+a}\right], |y| > b$$

$$C(x,y,z) = C_C(x) \exp\left[-\left(\frac{z}{S_z(x)}\right)^{1+a}\right], |y| \leq b$$

$$u_x = u_0\left(\frac{z}{z_0}\right)^a$$

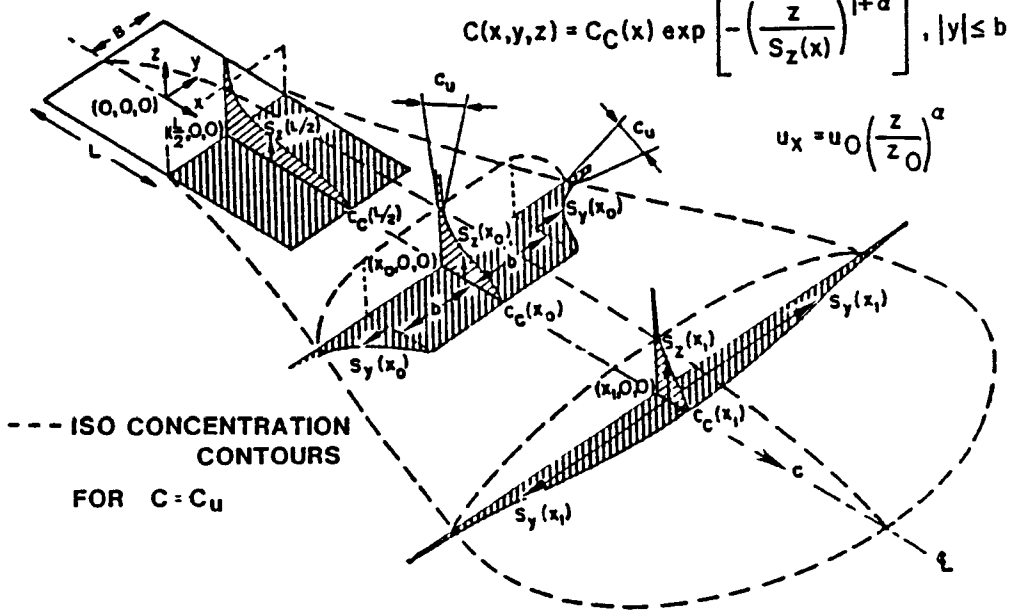


Figure V.1. Schematic Diagram of DEGADIS Dense Gas Dispersion Model.

$$u_f = C_E \left[g \left(\frac{\rho - \rho_a}{\rho_a} \right) H^2 \right]^{1/2} \qquad (V.1)$$

where ρ is the average density of the blanket for ($\rho > \rho_a$). $C_E = 1.15$, based on laboratory measurements of cloud spreading velocity (Havens and Spicer, 1985).

The blanket radius R is determined by integrating $dR/dt = u_f$. When the total mass of the blanket is decreasing with time (i.e., the atmospheric takeup exceeds the input rate from the primary source plus the air entrainment rate), the radius is modeled as $(dR/dt)/R = (dH/dt)/H$, with the radius of the blanket constrained to be greater than or equal to the primary source radius R_p.

Secondary Source Blanket Extent for Instantaneous Gas Releases

The gravity intrusion model (Equation (V.1)) overpredicts initial velocities for instantaneous, above-ground releases of a denser-than-air gas since the initial acceleration phase is not modeled. Consequently, the following procedure adapted from van Ulden (1983) is incorporated in DEGADIS.

For instantaneous gas releases, the radially symmetric cloud is considered to be composed of a tail section with height H_t and radius R_h and a head section with height H_h (Figure V.2). A momentum balance is used to account for the acceleration of the cloud from rest; the effect of ambient (wind) momentum is ignored. Although the following equations are derived assuming the absence of a primary source, the resulting equations are assumed to model the secondary source cloud development when the primary source rate is nonzero. When the frontal velocity from the momentum balance is the same as Equation (V.1), the momentum balance is no longer applied and the frontal velocity is given by Equation (V.1).

There are three main forces acting on the cloud: a static pressure force (F_p), a dynamic drag force (F_d), and a force which accounts for the acceleration reaction of the ambient fluid, represented as a rate of virtual momentum change with respect to time ($-dP_v/dt$). Denoting the momentum of the head and tail as P_h and P_t, respectively, the momentum balance is

$$\frac{dP}{dt} = \frac{d}{dt}(P_h + P_t) = F_p + F_d - \frac{dP_v}{dt} \qquad (V.2)$$

or

$$\frac{d}{dt}(P_h + P_t + P_v) = F_p + F_d \qquad (V.3)$$

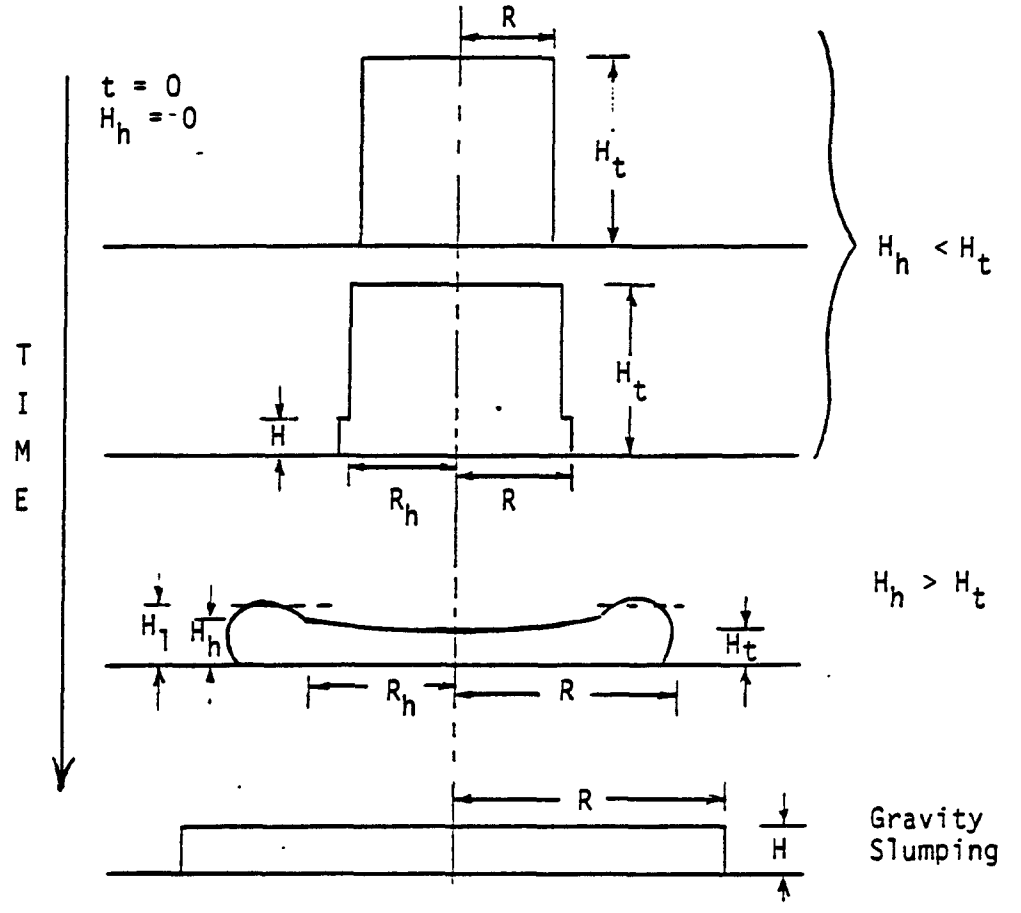

Figure V.2. Schematic Diagram of a Radially Spreading Cloud.

The terms in the momentum balance are evaluated differently for the time periods before a gravity current head has developed ($H_h < H_t$) and after the head has developed but the cloud is still accelerating (Figure V.2). Model equations describing the time period after the gravity current head forms ($H_h \geq H_t$) are derived first. The model equations describing the earlier time period ($H_h < H_t$) use simplifications of the equations applicable for $H_h \geq H_t$.

Unsteady Gravity Current ($H_h \leq H_t$)

When $H_h \geq H_t$ (Figures V.2, V.3), the frontal velocity is determined from the momentum balance (Equation (V.2)) as follows.

The static pressure force, obtained by integrating the static pressure over the boundary of the current, is

$$F_p = \left[\frac{1}{2} g\Delta\rho H_t \right] \left[2\pi R H_t \right] = \pi g\Delta\rho R H_t^2 \qquad (V.4)$$

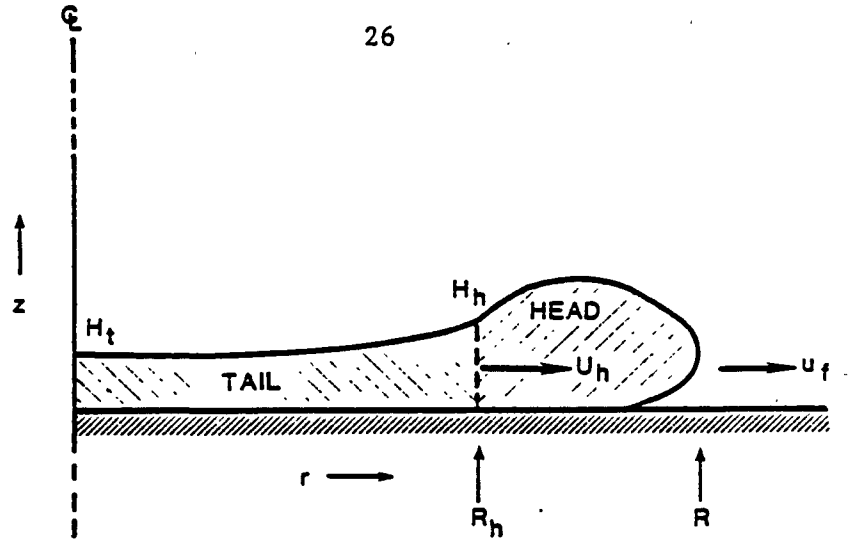

Figure V.3. The Unsteady Gravity Current (van Ulden, 1983).

Neglecting the shear stress at the bottom, the dynamic force on the current is the sum of the drag force on the head of the current and the lift force that arises due to asymmetry of the ambient flow around the head. The drag force is represented by

$$F_D = -\frac{d_v}{2}\rho_a u_f^2 \left(2\pi R_h a_v H_h \right) = -a_v d_v \pi R H_h \rho_a u_f^2 \qquad (V.5)$$

where d_v is an effective drag coefficient and the constant a_v is an empirical ratio of the average head depth H_1 to H_h ($a_v = H_1/H_h$).

The horizontal acceleration reaction ($-dP_v/dt$) is approximated by the reaction to an accelerating elliptical cylinder with an aspect ratio H/R (Batchelor, 1967):

$$-\left(\frac{dP_v}{dt} \right) = -\frac{d}{dt}\left(k_1 \rho_a \pi R H^2 u_f \right) \qquad (V.6)$$

and the vertical acceleration reaction is represented as

$$-\left(\frac{dP_v}{dt} \right)_z = -\frac{d}{dt}\left(k_2 \rho_a \pi R H^2 u_f \right) \qquad (V.7)$$

where k_1 and k_2 are coefficients of order one. Using a single constant, Equations (V.6) and (V.7) give

$$-\frac{dP_v}{dt} = -e_v \pi \rho_a \frac{d(RH^2 u_f)}{dt} \qquad (V.8)$$

Using Equations (V.4), (V.5), and (V.8), the momentum balance (Equation (V.2)) becomes

$$\frac{dP}{dt} = \pi g \Delta\rho R H_t^2 - a_v d_v \pi \rho_a R H_h u_f^2 - e_v \pi \rho_a \frac{d(RH^2 u_f)}{dt} \qquad (V.9)$$

Following van Ulden (1979, 1983), it is assumed that the potential energy decrease due to slumping of the cloud is offset by the production of kinetic energy, which through the action of shear is partly transformed to turbulent kinetic energy. Part of the turbulent kinetic energy is transformed back into potential energy due to entrainment of air by the cloud. This "buoyant destruction" of kinetic energy is assumed to be proportional to the rate of production of turbulent kinetic energy, and following Simpson and Britter (1979) it is assumed that the turbulent kinetic energy production rate scales as $\pi \rho_a H R u_f^3$. Then,

$$\frac{1}{2} g \Delta\rho H \frac{dV}{dt} = \epsilon \pi \rho_a H R u_f^3 \qquad (V.10)$$

which can be written

$$\frac{dV}{dt} = \frac{\epsilon (2\pi RH) u_f}{\left(\frac{g \Delta\rho H}{\rho_a u_f^2} \right)} = \frac{\epsilon (2\pi RH) u_f}{Ri_f} \qquad (V.11)$$

where ϵ is an empirical coefficient. Noting that dV/dt represents the air entrainment rate,

$$\frac{\dot{M}_a}{\rho_a} = \epsilon (2\pi RH) u_f \Big/ \left(\frac{g \Delta\rho H}{\rho_a u_f^2} \right) \qquad (V.12)$$

where $\dot{M}_a$ represents the air entrainment mass rate.

The volume integral

$$V = 2\pi \int_0^R h(r,t) r dr \qquad (V.13)$$

where h(r,t) is to be expressed in terms of H_h and H_t, and the momentum integral

$$P = 2\pi \int_0^R \rho u(r,t) h(r,t) r dr = P_t + P_h \qquad (V.14)$$

are then approximated with separate analyses of the head and tail of the current.

In the tail of the current, the shallow layer approximation is applied. It is assumed that the shape of the current is quasi-stationary in time, and the layer-averaged density difference is assumed horizontally uniform. It follows that the volume and momentum of the tail are given by

$$V_t = \pi R_h^2 \left[H_t + H_h \right] / 2. \tag{V.15}$$

$$P_t = \frac{2}{5} \rho \left[\frac{2}{3} H_t + H_h \right] \pi R_h^3 \frac{u_f}{R} \tag{V.16}$$

A momentum balance for the head region, Figure V.4, assuming quasi-steady state, indicates that the static and dynamic pressure forces on the head should be balanced by the net flux of momentum due to flow into and out of the head. The static pressure and drag are, respectively

$$F_p = \left[\frac{1}{2} g\Delta\rho H_h \right] \left[2\pi R_h H_h \right] = \pi g \Delta\rho R_h H_h^2 \tag{V.17}$$

and

$$F_D = - d_v \left[\frac{1}{2} \rho_a u_f^2 \right] \left[2\pi R_h (a_v H_h) \right]$$

$$= - a_v d_v \rho_a u_f^2 \pi R_h H_h \tag{V.18}$$

Near the surface, the inward flow (u_4 in Figure V.4) carries momentum into the head, while the return flow (u_3 in Figure V.4) carries momentum out of the head. Assuming $u_3 = u_4$, $H_4 = 1/2\ H_h$, and $u_4 = \delta_v u_f$, the momentum flux into the head is approximately

$$Q_h = \delta_v^2 \rho_a u_f^2 \left[2\pi R_h H_h \right] \tag{V.19}$$

Figure V.4. The Head of a Steady Gravity Current (Simpson and Britter, 1979; van Ulden, 1983).

Upon rearranging, the momentum balance on the head gives

$$\frac{\rho_a u_f^2}{g\Delta\rho H_h} = 1./\left[a_v d_v - 2\delta_v^2 \right] = C_E^2 \qquad (V.20)$$

when $\delta_v = 0.2$ and $d_v = 0.64$; Equation (V.20) then specifies the head velocity boundary condition. The volume of the head is determined by assuming that the head length scales with H_1. It follows that

$$R - R_h = b_v H_1 \qquad (V.21)$$

where b_v is an empirical constant, and the volume of the head becomes

$$V_h = \pi a_v^2 b_v (R + R_h) H_h^2 \qquad (V.22)$$

If the layer-averaged velocity is assumed to increase linearly with r, it follows that

$$u_h = u_f \left(\frac{R_h}{r} \right) \qquad (V.23)$$

and

$$P_h = \frac{2\pi}{3} \rho a_v \frac{u_f H_h}{R} \left[R^3 - R_h^3 \right] \qquad (V.24)$$

Along with the definition of u_f,

$$\frac{dR}{dt} = u_f, \qquad (V.25)$$

Equations (V.9), (V.11), (V.20), (V.21), (V.23), and (V.25) are solved to determine ρ, H_t, H_h, V, P_h, and P_t when $H_h > H_t$.

The constants a_v, b_v, d_v, e_v, and ϵ are assigned values 1.3, 1.2, 0.64, 20., and 0.59, respectively, based on analysis of the still-air denser-than-air gas release experiments of Havens and Spicer (1985).

Initial Gravity Current Development ($H_h < H_t$)

In order to model the initial cloud shape, the tail and head height are considered constant with respect to radius. The momentum balance on the cloud is then given by

$$\frac{d}{dt}\left[P_h + P_t \right] = \pi g \Delta\rho \left[R_h H_t^2 + a_v b_v H_h^3 \right] - \pi a_v d_v \rho_a R H_h u_f^2 - \frac{dP_v}{dt} \qquad (V.26)$$

where the first term on the right-hand side represents the static pressure force on the head and the second term represents the drag force on the bottom surface of the cloud. The third force is the acceleration reaction by the ambient fluid, represented by Equation (V.8).

The dimensions of the head are again given by

$$R_h = R - a_v b_v H_h \tag{V.27}$$

and

$$H_h = \left[\frac{u_f}{C_E} \right]^2 \Big/ \left[g\Delta\rho/\rho_a \right] \tag{V.28}$$

When the height of the tail H_t is assumed uniform with respect to radius, it follows that

$$H_t = \left[\frac{M}{\rho} - \pi a_v^2 b_v \left(R + R_h\right) H_h^2 \right] \Big/ \left(\pi R_h^2\right) \tag{V.29}$$

where M is the total mass of the cloud. The momentum of the head P_h and tail P_t are then

$$P_h = \frac{2}{3} \pi a_v \frac{\rho H_h \left(R^3 - R_h^3\right)}{R} u_f \tag{V.30}$$

and

$$P_t = \frac{2}{3} \pi \frac{\rho H_t R_h^3}{R} u_f \tag{V.31}$$

Equations (V.26) through (V.31) determine the momentum of the blanket as a function of time, and thus the frontal velocity u_f. The cloud accelerates from rest because $H_h = 0$ initially.

Material and Energy Balances

The balance on the total mass of gas in the source blanket ($M = \pi R^2 H \rho$) is

$$\frac{dM}{dt} = \frac{d}{dt} \left[\pi R^2 H \rho \right] = \frac{E(t)}{w_{c,p}(t)} + \dot{M}_a + \dot{M}_{w,s} - \left[\frac{Q_{*max}}{w_c} \right] \left[\pi R^2 \right] \tag{V.32}$$

where E(t) is the contaminant evolution rate from the primary (liquid) source and $w_{c,p}(t)$ is the contaminant mass fraction in the primary source. For spills onto water, the water entrainment term ($\dot{M}_{w,s}$) is included in the source blanket description and is calculated from

Equation (V.46), and the (humid) air entrainment rate (Equation (V.12)) is

$$\dot{M}_a = 2\pi RH(\epsilon u_f)\rho_a \Big/ \left[g\Delta\rho H/(\rho_a u_f^2) \right] \tag{V.33}$$

The balance on the mass of contaminant in the source blanket $(M_c = w_c \pi R^2 H\rho)$ is

$$\frac{dM_c}{dt} = \frac{d}{dt}\left[w_c \pi R^2 H\rho \right] = E(t) - Q_{*max}\,(\pi R^2) \tag{V.34}$$

and the mass balance on the air in the source blanket $(M_a = w_a \pi R^2 H\rho)$ is

$$\frac{dM_a}{dt} = \frac{d}{dt}\left[w_a \pi R^2 H\rho \right] = \frac{E(t)}{w_{c,p}(t)}\left[\frac{1 - w_{c,p}(t)}{1 + H_a} \right] + \frac{\dot{M}_a}{1 + H_a} - \left[\frac{\dot{Q}_{*max}}{w_c} \right] w_a\,(\pi R^2) \tag{V.35}$$

where the ambient humidity is H_a and the mass fraction of contaminant and air are $w_c = M_c/M$ and $w_a = M_a/M$, respectively. Note that any dilution of the primary source with air is assumed to be at ambient humidity.

The energy balance on the source blanket $(h\pi R^2 H\rho)$ gives

$$\frac{d}{dt}\left[h\pi R^2 H\rho \right] = \frac{h_p\, E(t)}{w_{c,p}(t)} + h_a \dot{M}_a + h_w \dot{M}_{w,s} - h\left[\frac{\dot{Q}_{*max}}{w_c} \right](\pi R^2) + \dot{Q}_s \tag{V.36}$$

where h_p is the enthalpy of the primary source gas, h_a is the enthalpy of the ambient humid air, and h_w is the enthalpy of any water vapor entrained by the blanket (if on water). There are three alternate submodels included for heat transfer ($\dot{Q}_s$) from the surface to the cloud.

The simplest method for calculating the heat transfer between the substrate and the gas cloud is to specify a constant heat transfer coefficient for the heat transfer relation

$$\dot{Q}_s = q_s\left[\pi\left(R^2 - R_p^2 \right) \right] = h_0 \Delta T\left[\pi\left(R^2 - R_p^2 \right) \right] \tag{V.37}$$

where $\dot{Q}_S$ is the rate of heat transfer to the cloud, q_S is the heat flux, and ΔT is the temperature difference between the cloud and the surface. For the calculation of heat transfer over the source, the temperature difference is based on the average temperature of the blanket.

In the evaluation of the Burro and Coyote series of experiments, Koopman et al. (1981) proposed the following empirical heat transfer coefficient relationship for heat transfer between a cold LNG vapor cloud and the ground

$$h_0 = V_H \rho C_p \tag{V.38}$$

where the value of V_H was estimated to be 0.0125 m/s. (The constant V_H can be specified in this model.)

From the heat transfer coefficient descriptions for heat transfer from a flat plate, the following relationships can be applied. For natural convection, the heat transfer coefficient is estimated using the Nusselt (Nu), Grashoff (Gr), and Schmidt (Sc) numbers (McAdams, 1954) from

$$Nu = 0.14\ (Gr\ Sc)^{1/3} \tag{V.39}$$

or

$$h_n = 0.14 \left[\frac{g \rho^2 C_p^3 \mu}{T\ Pr^2} \Delta T \right]^{1/3} \tag{V.40}$$

where h_n is the natural convection heat transfer coefficient and Pr is the Prandtl number. In order to simplify the calculations, the parameter group

$$\left[Pr^{-2} \left(C_p MW \right)^3 \left(\frac{\mu}{MW\ T} \right) \right]^{1/3} \tag{V.41}$$

is estimated to be 60 in mks units (actual values are 47.25, 58.5, and 73.4 for air, methane, and propane, respectively). Equation (V.40) becomes

$$h_n = 18 \left[\left(\frac{\rho}{MW} \right)^2 \Delta T \right]^{1/3} \tag{V.42}$$

where the density ρ, molecular weight MW, and temperature difference ΔT are based on the average composition of the gas blanket.

For forced convection, the Colburn analogy (Treybal, 1980) is applied to a flat plate using the Stanton number for heat transfer St_H and the Prandtl number as

$$St_H \, Pr^{2/3} = \frac{c_f}{2} = \left(\frac{u_*}{\bar{u}} \right)^2 \tag{V.43}$$

or

$$h_f = (\bar{u}\rho C_p) \, Pr^{-2/3} \left(\frac{u_*}{\bar{u}} \right)^2 \tag{V.44}$$

where h_f is the forced convection heat transfer coefficient. If the velocity is evaluated at z = H/2 and Pr is specified 0.741,

$$h_f = \left[1.22 \, \frac{u_*^2}{u_0} \left(\frac{2z_0}{H} \right)^{\alpha} \right] \rho C_p \tag{V.45}$$

If $H/2 < z_R$, then the velocity is evaluated at $z = z_R$.

The overall heat transfer coefficient is then the maximum of the forced and natural convection coefficients, i.e. $h_0 = \max(h_f, h_n)$. The heat flux and transfer rate are then estimated by Equation (V.37).

If the gas blanket is formed over water, water may be transferred from the water surface to the blanket. The rate of mass transfer of water is modeled as

$$\dot{M}_{w,s} = \frac{F_0}{p} \left(p^*_{w,s} - p_{w,c} \right) \left[\pi \left(R^2 - R_p^2 \right) \right] \tag{V.46}$$

where F_0 is an overall mass transfer coefficient. The partial pressure driving force is the difference of the vapor pressure of water at the surface temperature $p^*_{w,s}$ and the partial pressure of water in the cloud, $p_{w,c}$. (The water partial pressure in the cloud is the minimum of: (a) the water mole fraction times the ambient pressure; or (b) the water vapor pressure at the cloud temperature ($p^*_{w,c}$).) The natural convection coefficient is based on the heat transfer coefficient and the analogy between the Sherwood number (Sh) and the Nusselt number (Nu) suggested by Bird et al. (1960)

$$Sh = Nu = 0.14 \, (Gr \, Sc)^{1/3} = \frac{F_n L}{D'} \left(\frac{MW}{\rho} \right) \tag{V.47}$$

If the Schmidt number is taken as 0.6, and $\left(\frac{\mu}{T \, MW} \right)$ is estimated to be 2.2×10^{-9} in mks units,

$$F_n = 9.9 \times 10^{-3} \left[\left(\frac{\rho}{MW} \right)^2 \Delta T \right]^{1/3} \tag{V.48}$$

For forced convection, Treybal (1980) suggests that the Stanton number for mass transfer St_M and the Stanton number for heat transfer St_H are related by

$$St_M = St_H \left[\frac{Pr}{Sc} \right]^{2/3} = 1.15\ St_H \tag{V.49}$$

or,

$$F_f = \frac{20.7\ h_0}{MW\ C_p} \tag{V.50}$$

The overall mass transfer coefficient F_0 is the larger of the natural and forced convection coefficients.

For the case when the primary (liquid) source emission rate E(t) is larger than the atmospheric takeup rate $Q_{*max}\pi R_p^2$, Equations (V.32), (V.34), (V.35), and (V.36) are integrated for the mass, concentration, and enthalpy of the gas blanket along with an appropriate equation of state (i.e. relationship between enthalpy and temperature and between temperature and density).

When the emission rate is not sufficient to form a gas blanket, the flux of contaminant is not determined by the maximum atmospheric takeup rate. Consider the boundary layer formed by the emission of gas into the atmosphere above the primary source. If the source is modeled to have a uniform width 2b and entrain no air along the sides of the layer, the balance on the total material ($\rho_L u_L H_L$) in a differential slice of the layer is

$$\frac{d}{dx}\left[\rho_L u_L H_L \right] = \rho_a w_e + \left[\frac{Q_*}{w_c} \right]_p \tag{V.51}$$

where w_e is the vertical rate of of air entrainment into the layer given by Equation (V.83), ρ_L is the average density of the slice, and $(Q_*/w_c)_p$ is the total flux of gas from the primary source. The balance on the mass flow rate of contaminant ($w_c \rho_L u_L H_L$) at any ($x - x_{up}$) is

$$c_{c,L} u_L H_L = Q_*(x - x_{up}) \tag{V.52}$$

With an equation of state to relate $c_{c,L}$ and ρ_L, Equation (V.51) is integrated from the upwind edge of the source ($x = x_{up}$) to the downwind edge ($x = L + x_{up}$).

In order to generate the initial conditions for the downwind dispersion calculations, the maximum concentration c_c and the vertical dispersion parameter S_z are needed. Since Equations (V.51) and (V.52) are written for a vertically averaged layer, consider the vertical average of the power law distribution. The height of the layer H_L is the height to some concentration level, say 10% of the maximum. Although strictly a function of α, this value is modeled as

$$H_L = \delta_L H_{EFF} \tag{V.53}$$

where H_{EFF} is the effective height defined by Equation (V.79) and $\delta_L = 2.15$. The vertically averaged concentration $c_{c,L}$ is defined by

$$c_{c,L} H_L = \int_0^\infty c\,dz \tag{V.54}$$

Similarly, the effective transport velocity u_L is defined by

$$c_{c,L} u_L H_L = \int_0^\infty c u_x\,dz \tag{V.55}$$

With Equation (V.53) and defining relations for H_{EFF} and u_{EFF} (Equations (V.79) and (V.93), respectively), it follows that

$$c_c = \delta_L c_{c,L} \tag{V.56}$$

$$u_L H_L = \delta_L \left(\frac{u_0 z_0}{1 + \alpha} \right) \left(\frac{S_z}{z_0} \right)^{1+\alpha} \tag{V.57}$$

and

$$\delta_L w'_e = w_e \tag{V.58}$$

where w'_e is given by Equation (V.83).

Maximum Atmospheric Takeup Rate

The maximum atmospheric takeup rate is determined as the largest takeup rate which satisfies Equations (V.51) and (V.52), and the maximum concentration of contaminant at the downwind edge of the source is the source contaminant concentration $(c_c)_s$. Combining Equations (V.51) and (V.52) and assuming adiabatic mixing of ideal gases with equal molal heat capacities (i.e. $(\rho - \rho_a)/c_c = \gamma$ = constant), the maximum takeup flux is modeled as

$$Q_{*max} = (c_c)_s \frac{k u_* (1 + \alpha)}{\hat{\phi}} \left(\frac{\delta_L}{\delta_L - 1} \right) \tag{V.59}$$

where

$$\frac{1}{\hat{\phi}} = \frac{1}{L} \int_0^L \frac{dx}{\phi(Ri_*)} \tag{V.60}$$

and $\phi(Ri_*)$ is defined (for $\rho \geq \rho_a$) by Equation (V.76).

An upper bound for the atmospheric takeup flux can be associated with the condition where the source begins to spread as a gravity intrusion against the approach flow. In water flume experiments, Britter (1980) measured the upstream and lateral extent of a steady-state plume from a circular source as a function of Ri_*. A significant upstream spread was obtained for $Ri_* > 32$, and lateral spreading at the center of the source was insignificant for $Ri_* < 8$. The presence of any significant lateral spreading represents a lower bound on the conditions of the maximum takeup flux.

The integral of Equation (V.60) is evaluated using a local Richardson number

$$Ri_*(x) = \varsigma(x - x_{up})^{\frac{1}{1+\alpha}} \tag{V.61}$$

where

$$\varsigma = g\left[\frac{\rho - \rho_a}{\rho_a}\right]\frac{z_0}{u_*^2}\frac{\Gamma\left(\frac{1}{1+a}\right)}{1+\alpha}\left[\frac{ku_*(1+\alpha)}{\phi_c}\left[\frac{1+\alpha}{u_0 z_0}\right]\left[\frac{\delta_L}{\delta_L - 1}\right]\right]^{\frac{1}{1+\alpha}} \tag{V.62}$$

and ϕ_c is 3.1 (corresponding to $Ri_* = 20 (8 < Ri_* < 32)$). Equation (V.60) then becomes

$$\frac{1}{\hat{\phi}} = \frac{1}{L}\int_0^L \frac{dx}{0.88 + 0.099\ \varsigma^{\frac{1.04}{1+\alpha}} x^{1.04}} \tag{V.63}$$

Equation (V.63) can be solved analytically (Gradshteyn and Ryzhik, 1980). With $\hat{\phi}$ determined, Q_{*max} can be determined with Equation (V.59).

Simulation of Transient Gas Releases

For simulating steady-state releases, the transient source calculation is carried out until the source characteristics no longer change (significantly) with time. The maximum centerline concentration c_c, the horizontal and vertical dispersion parameters S_y and S_z, the half width b, and if necessary, the enthalpy h are used as initial conditions for the downwind calculation specified in a transient spill.

Transient releases are modeled as a series of pseudo-steady-state releases. Consider a series of observers traveling with the wind over

the transient gas source described above; each observer originates from the point which corresponds with the maximum upwind extent of the gas blanket ($x = -R_{max}$). The observer velocity is u_{EFF} (Equation (V.93)), the average transport velocity of the gas. Since, in general, the value of u_{EFF} may differ from observer to observer, observer separation is not guaranteed. For a neutrally buoyant cloud, u_{EFF} is a function of downwind distance alone, and observer separation is guaranteed. Following Colenbrander (1980), the observer velocity is modeled as:

$$u_i(x) = \frac{u_0}{\Gamma\left(\frac{1}{1+\alpha}\right)} \left[\frac{S_{z_{0m}}}{z_0}\right]^{\alpha} \left[\frac{x + R_{max}}{\frac{\sqrt{\pi}}{2} R_m + R_{max}}\right]^{\alpha/(1+\alpha)} \tag{V.64}$$

where $S_{z_{0m}}$ is the value of S_{z_0} when the averaged source rate ($\pi R^2 Q_*$) is a maximum, and the subscript i denotes observer i. Noting that $u_i(x) = dx_i/dt$, observer position and velocity are determined.

A pseudo-steady-state approximation of the transient source is determined as each observer passes over the source. If t_{up_i} and t_{dn_i} denote the times when observer i encounters the upwind and downwind edges of the source respectively, then the source fetch seen by observer i is:

$$L_i = x_{up_i} - x_{dn_i} \tag{V.65}$$

The width of the source $2B_i'(t)$ is defined by

$$B_i'^2(t) = R^2(t) - x_i^2(t) \tag{V.66}$$

Then the gas source area seen by observer i is

$$2L_i b_i = 2 \int_{t_{up_i}}^{t_{dn_i}} B_i' u_i dt \tag{V.67}$$

where $2b_i$ is the average width.

The takeup rate of contaminant $2(Q_* Lb)_i$ is calculated as

$$2(Q_* Lb)_i = 2 \int_{t_{up_i}}^{t_{dn_i}} Q_* B_i' u_i dt \tag{V.68}$$

The total mass flux rate from the source is

$$2(\rho_L u_L H_L b)_i = 2 \int_{t_{up_i}}^{t_{dn_i}} \left[\rho_a w'_e + \left(\frac{Q_*}{w_c} \right) \right] B'_i u_i dt \qquad (V.69)$$

The average composition of the layer can now be determined at each $x - x_{up}$ over the source. The enthalpy of the layer is given by

$$2(h_L \rho_L u_L H_L b)_i = 2 \int_{t_{up_i}}^{t_{dn_i}} h \left(\frac{Q_*}{w_c} \right) B'_i u_i dt \qquad (V.70)$$

(due to the choice of the reference temperature as the ambient temperature). With a suitable equation of state relating enthalpy, temperature, and density, the source can be averaged for each observer. After the average composition of the layer is determined at the downwind edge, an adiabatic mixing calculation is performed for gas of the layer average concentration and the ambient air. This calculation determines the function between density and concentration relationship for the remainder of the simulation if the calculation is adiabatic; it represents the adiabatic mixing condition if heat transfer is included in the downwind simulation.

For each of several observers released successively from $x = -R_{max}$, the observed dimensions L and b, the downwind edge of the source x_{dn}, the average vertical dispersion coefficient S_z, the average takeup flux Q_*, the centerline concentration c_c, and if applicable, the average enthalpy h_L is determined. A steady-state calculation is then made for each observer. The distribution parameters for any specified time t_s are determined by locating the position of the series of observers at time t_s, i.e. $x_i(t_s)$. The corresponding concentration distribution is then computed from the assumed profiles.

Steady-State Downwind Dispersion

The model treats dispersion of gas entrained into the wind field from an idealized, rectangularly shaped source of width 2b and length L. The circular source cloud is represented as an equivalent area rectangle ($\pi R^2 = 2bL$) with equivalent fetch ($L = 2R$). Similarity forms for the concentration profiles represent the plume as a horizontally homogeneous center section with Gaussian concentration profile edges:

$$c(x,y,z) = c_c(x) \exp \left[- \left(\frac{|y| - b(x)}{S_y(x)} \right)^2 - \left(\frac{z}{S_z(x)} \right)^{1+\alpha} \right]$$

for $|y| > b$

$$= c_c(x) \exp\left[- \left(\frac{z}{S_z(x)} \right)^{1+\alpha} \right] \qquad \text{for } |y| \leq b \tag{V.71}$$

A power law wind velocity profile is assumed

$$u_x = u_0 \left(\frac{z}{z_0} \right)^{\alpha} \tag{V.72}$$

where the value of α is determined by a weighted least-squares fit of the logarithmic profile

$$u_x = \frac{u_*}{k} \left[\ln \left(\frac{z + z_R}{z_R} \right) - \Psi \left(\frac{z}{\lambda} \right) \right] \tag{V.73}$$

Functional forms for Ψ and typical values of α are given in Table V.1 for different Pasquill stability categories. With these profiles, the parameters of Equation (V.71) are constrained by ordinary differential equations.

TABLE V.1

F	$26.0\ z_R^{0.17}$	0.253	

[1]Curve fit of data from Pasquill (1974).

Vertical Dispersion

The vertical dispersion parameter S_z is determined by requiring that it satisfy the diffusion equation

$$u_x \frac{\partial c}{\partial x} = \frac{\partial}{\partial z} K_z \frac{\partial c}{\partial z} \tag{V.74}$$

with the vertical turbulent diffusivity given by

$$K_z = \frac{k u_* z}{\phi(Ri_*)} \tag{V.75}$$

The function $\phi(Ri_*)$ is a curve fit of laboratory data for vertical mixing in stably density-stratified fluid flows ($Ri_* > 0$) reported by Kantha et al. (1977), Lofquist (1960), and McQuaid (1976). For $Ri_* < 0$, the function $\phi(Ri_*)$ was taken from Colenbrander and Puttock (1983) and modified so the passive limit of the two functions agree as follows:

$$\begin{aligned} \phi(Ri_*) &= 0.88 + 0.099\ Ri_*^{1.04} && Ri_* \geq 0 \\ &= 0.88/(1 + 0.65\ |Ri_*|^{0.6}) && Ri_* < 0 \end{aligned} \tag{V.76}$$

The friction velocity is calculated using Equation (V.73) from a known velocity u_0 at a specific height z_0. Combining the assumed similarity forms for concentration and velocity, Equations (V.71), (V.72), (V.74), and (V.75) give

$$\frac{d}{dx}\left[\left(\frac{u_0 z_0}{1+\alpha}\right)\left(\frac{S_z}{z_0}\right)^{1+\alpha}\right] = \frac{k u_*(1+\alpha)}{\phi(Ri_*)} \tag{V.77}$$

where the Richardson number Ri_* is computed as

$$Ri_* = g\left(\frac{\rho - \rho_a}{\rho_a}\right)\frac{H_{EFF}}{u_*^2} \tag{V.78}$$

and the effective cloud depth is defined as

$$H_{EFF} = \frac{1}{c_c}\int_0^\infty c\,dz = \Gamma\left(\frac{1}{1+\alpha}\right)\frac{S_z}{1+\alpha} \tag{V.79}$$

Equation (V.77) can be viewed as a volumetric balance on a differential slice downwind of the source. A mass balance over the same slice gives,

$$\frac{d}{dx}\left(\rho_L u_L H_L\right) = \rho_a w_e \tag{V.80}$$

which is Equation (V.51) without the source term. With Equations (V.57) and (V.58), this becomes

$$\frac{d}{dx}\left(\rho_L u_{EFF} H_{EFF}\right) = \rho_a w_e' \tag{V.81}$$

Assuming adiabatic mixing of ideal gases with equal constant molal heat capacities (i.e. $(\rho - \rho_a)/c_c$ = constant) and using the contaminant mass balance, the mass balance becomes

$$\frac{d}{dx}\left(u_{EFF} H_{EFF} \right) = w'_e \tag{V.82}$$

which leads to

$$w'_e = \frac{w_e}{\delta_L} = \frac{k u_* (1 + \alpha)}{\phi(Ri_*)} \tag{V.83}$$

Equations (V.81) and (V.83) are combined to give

$$\frac{d}{dx}\left(\rho_L u_{EFF} H_{EFF} \right) = \frac{\rho_a k u_* (1 + \alpha)}{\phi(Ri_*)} \tag{V.84}$$

Generalizing, Equation (V.84) is assumed to apply when $(\rho_a - \rho_c)/c$ is not constant.

When heat transfer from the surface is present, vertical mixing will be enhanced by the convection turbulence due to heat transfer. Zeman and Tennekes (1977) model the resulting vertical turbulent velocity as

$$\frac{w}{u_*} = \left[1 + \frac{1}{4}\left(\frac{w_*}{u_*} \right)^2 \right]^{1/2} \tag{V.85}$$

where w_* is the convective scale velocity described as

$$\left(\frac{w_*}{u_*} \right)^2 = \left[\frac{gh}{u_* \bar{u}} \frac{\left(T_s - T_{c,L} \right)}{T_{c,L}} \right]^{2/3} \tag{V.86}$$

If $\bar{u}$ is is evaluated at H_{EFF},

$$\frac{w}{u_*} = \left(1 + \frac{1}{4} Ri_T^{2/3} \right)^{1/2} \tag{V.87}$$

where

$$Ri_T = g \left(\frac{T_s - T_{c,L}}{T_{c,L}} \right) \frac{H_{EFF}}{u_* u_0} \left(\frac{z_0}{H_{EFF}} \right)^{\alpha} \tag{V.88}$$

and $T_{c,L}$ is the temperature obtained from the energy balance of Equations (V.103) and (V.104). Equation (V.84) is modified to account for this enhanced mixing by

$$\frac{d}{dx}\left[\rho_L u_{EFF} H_{EFF}\right] = \frac{\rho_a kw(1+\alpha)}{\phi(Ri'_*)} \tag{V.89}$$

where $Ri'_* = Ri_* \left[\frac{u_*}{w}\right]^2$.

Although derived for two-dimensional dispersion, Equation (V.89) is extended for application to a denser-than-air gas plume which spreads laterally as a density intrusion:

$$\frac{d}{dx}\left[\rho_L u_{EFF} H_{EFF} B_{EFF}\right] = \frac{\rho_a kw(1+\alpha)}{\phi(Ri'_*)} B_{EFF} \tag{V.90}$$

where the plume effective half width is defined by

$$B_{EFF} = b + \frac{\sqrt{\pi}}{2} S_y \tag{V.91}$$

and determined using the gravity intrusion relation

$$\frac{dB_{EFF}}{dt} = C_E \left[g \left(\frac{\rho - \rho_a}{\rho_a} \right) H_{EFF} \right]^{1/2} \tag{V.92}$$

The average transport velocity in the plume is defined by

$$u_{EFF} = \frac{\int_0^\infty cu_x dz}{\int_0^\infty c dz} = u_0 \left[\frac{S_z}{z_0}\right]^\alpha \Big/ \Gamma\left(\frac{1}{1+\alpha}\right) \tag{V.93}$$

and the lateral spread of the cloud is modeled as

$$\frac{dB_{EFF}}{dx} = \frac{1}{u_{EFF}} \frac{dB_{EFF}}{dt}$$

$$= C_E \left[\frac{g z_0 \Gamma^3 \left(\frac{1}{1+\alpha} \right)}{u_0^2 (1 + \alpha)} \right]^{1/2} \left(\frac{\rho - \rho_a}{\rho_a} \right)^{1/2} \left(\frac{S_z}{z_0} \right)^{\left(\frac{1}{2} - \alpha \right)} \qquad (V.94)$$

Horizontal Dispersion

The crosswind similarity parameter $S_y(x)$ is also determined by requiring that it satisfy the diffusion equation

$$u_x \frac{\partial c}{\partial x} = \frac{\partial}{\partial y} \left[K_y \frac{\partial c}{\partial y} \right] \qquad (V.95)$$

with the horizontal turbulent diffusivity given by

$$K_y = K_0 u_x B_{EFF}^{\gamma_1} \qquad (V.96)$$

For a passive plume (b = 0), $S_y = \sqrt{2}\sigma_{y,a}$ where $\sigma_{y,a}$ is the similarity parameter correlated by Pasquill (1974) in the form $\sigma_{y,a} = \delta_y x^{\beta_y}$ where δ_y and β_y are functions of the Pasquill stability category and the averaging time. Furthermore, Equations (V.95) and (V.96) require that

$$\sigma_{y,a} \frac{d\sigma_{y,a}}{dx} = K_0 B_{EFF}^{\gamma_1} \qquad (V.97)$$

where $\gamma_1 = 2 - 1/\beta_y$ and $K_0 = \frac{2\beta_y}{\pi} (\delta_y \sqrt{\pi/2})^{1/\beta_y}$. Then,

$$S_y \frac{dS_y}{dx} = \frac{4\beta_y}{\pi} B_{EFF}^2 \left[\frac{\delta_y \sqrt{\pi/2}}{B_{EFF}} \right]^{1/\beta_y} \qquad (V.98)$$

where Equation (V.98) is also assumed applicable for determining S_y when b is not zero.

At the downwind distance x_t where b = 0, the crosswind concentration profile is assumed Gaussian with S_y given by

$$S_y = \sqrt{2}\, \delta\, (x_y + x_v)^{\beta} \qquad (V.99)$$

where x_v is a virtual source distance determined as

$$S_y(x_t) = \sqrt{2}\, \delta_y (x_t + x_v)^{\beta} \qquad (V.100)$$

The gravity spreading calculation is terminated for $x > x_t$.

Averaging Time

The observed dispersion of a gas plume is a function of the observation (averaging) time. Herein we have assumed:

-- The most important influence of averaging time on observed plume properties is associated with plume meander.
-- For ground-level releases, vertical plume meander is much smaller than horizontal plume meander.

Gifford (1960) showed that the ratio of maximum measured concentrations based on different averaging times (t_a and t_p) was given by

$$\frac{c_c(t_p)}{c_c(t_a)} = \left[\frac{t_a}{t_p}\right]^{0.2}$$

for t_a/t_p up to about 200, when source and receptor were at the same level. Spicer and Havens (1988) proposed that

$$\frac{\sigma_{y,a}(t_a)}{\sigma_{y,a}(t_{a,i})} \simeq \left[\frac{t_a}{t_{a,i}}\right]^{0.2}$$

where $t_{a,i}$ was suggested to be an "instantaneous" averaging time representing the smallest time scale associated with plume meander. (Practically, $t_{a,i}$ represents a nonzero averaging time associated with the puff coefficient $\sigma_{y,a}(t_{a,i})$.) Based on correlations from Gifford (1976) and Slade (1968), Spicer and Havens (1988) presented the following dispersion coefficient correlations for stabilities A through F:

$$\sigma_{y,a}(x;t_a) = 0.423 \left[\frac{t_a^*}{600\ s}\right]^{0.2} x^{0.9} \qquad A \qquad \text{(V.101a)}$$

$$\sigma_{y,a}(x;t_a) = 0.313 \left[\frac{t_a^*}{600\ s}\right]^{0.2} x^{0.9} \qquad B \qquad \text{(V.101b)}$$

$$\sigma_{y,a}(x;t_a) = 0.210 \left[\frac{t_a^*}{600\ s}\right]^{0.2} x^{0.9} \qquad C \qquad \text{(V.101c)}$$

$$\sigma_{y,a}(x;t_a) = 0.136 \left[\frac{t_a^*}{600\ s}\right]^{0.2} x^{0.9} \qquad D \qquad \text{(V.101d)}$$

$$\sigma_{y,a}(x;t_a) = 0.102 \left[\frac{t_a^*}{600\ s}\right]^{0.2} x^{0.9} \qquad E \qquad \text{(V.101e)}$$

$$\sigma_{y,a}(x;t_a) = 0.0674 \left[\frac{t_a^*}{600\ s} \right]^{0.2} x^{0.9} \qquad F \qquad \text{(V.101f)}$$

where $t_a^* = \max(t_a, t_{a,i})$ and t_a is the desired averaging time. Values of $t_{a,i}$ are shown in Table V.2.

Table V.2. Values of $t_{a,i}$ for Use in Eq. (V.101)

Pasquill Stability	$t_{a,i}$(s)
A	18.4
B	18.4
C	18.4
D	18.3
E	11.4
F	4.6

Values for δ_y and β_y are then determined by Equation (V.101). (For example, for an averaging time of 60 s for F stability, $t_a^* = 60$ s, $\delta_y = 0.0425$, and $\beta_y = 0.9$.)

(Thermal) Energy Balance

For some simulations of cryogenic gas releases, heat transfer to the plume in the downwind dispersion calculation may be important, particularly in low wind conditions. The source calculation determines a gas/air mixture initial condition for the downwind dispersion problem. Air entrained into the plume is assumed to mix adiabatically. Heat transfer to the plume downwind of the source adds additional heat. This added heat per unit mass D_h is determined by an energy balance on a uniform cross-section as

$$\frac{d}{dx}\left[D_h \rho_L u_{EFF} H_{EFF} \right] = q_s/\delta_L \qquad \text{(V.102)}$$

where q_s is determined by Equation (V.37) along with the desired method of calculating h_0. Equation (V.102) is applied when $b = 0$ and is generalized to

$$\frac{d}{dx}\left[D_h \rho_L u_{EFF} H_{EFF} B_{EFF} \right] = q_s B_{EFF}/\delta_L \qquad \text{(V.103)}$$

when $b > 0$. Since the average density of the layer ρ_L cannot be determined until the temperature (i.e. D_h) is known, a trial and error procedure is required.

Closure

For a steady plume, the centerline concentration c_c is determined from the material balance

$$E = \int_0^\infty \int_{-0}^\infty cu_x dydz = 2c_c \left[\frac{u_0 z_0}{1 + \alpha} \right] \left[\frac{S_z}{z_0} \right]^{1+\alpha} B_{EFF} \qquad (V.104)$$

where E is the plume source strength.

Equations (V.76), (V.78), (V.79), (V.85)-(V.91), (V.93), (V.94), (V.98)-(V.100), and (V.102)-(V.104) are combined with an equation of state relating cloud density to gas concentration and temperature and are solved simultaneously to predict S_z, S_y, c_c, and b as functions of downwind distance beginning at the downwind edge of the gas source.

Correction for Along-Wind Dispersion

Following Colenbrander (1980), an adjustment to c_c is applied to account for dispersion parallel to the wind direction. The calculated centerline concentration $c_c(x)$ is considered to have resulted from the release of successive planar puffs of gas ($c_c(x)\Delta x$) without any dispersion in the x-direction. If it is assumed that each puff diffuses in the x-direction as the puff moves downwind independently of any other puff and that the dispersion is one-dimensional and Gaussian, the x-direction concentration dependence is given by

$$c_c'(x;x_{p_i}) = \frac{c_c(x_{p_i})\Delta x_i}{\sqrt{2\pi}\,\sigma_{x,a}} \exp\left[-\frac{1}{2} \left[\frac{x - x_{p_i}}{\sigma_x} \right]^2 \right] \qquad (V.105)$$

where x_{p_i} denotes the position of the puff center due to observer i.

After Beals (1971), the x-direction dispersion coefficient $\sigma_{x,a}$ is assumed to be a function of distance from the downwind edge of the gas source ($X = x - x_0$) and atmospheric stability given by

$$\begin{aligned} \sigma_{x,a}(X) &= 0.02\, X^{1.22} && \text{unstable, } x \geq 130 \text{ m} \\ &= 0.04\, X^{1.14} && \text{neutral, } x \geq 100 \text{ m} \\ &= 0.17\, X^{0.97} && \text{stable, } x \geq 50 \text{ m} \end{aligned} \qquad (V.106)$$

where ($X = x - x_0$) and $\sigma_{x,a}$ are in meters. The concentration at x is then determined by superposition, i.e., the contribution to c_c at a given x from neighboring puffs is added to give an x-direction corrected value of c_c'. For N observers,

$$c_c'(x) = \sum_{i=1}^{N} \frac{c_c(x_{p_i})}{\sqrt{2\pi}\,\sigma_{x,a}} \exp\left[-\frac{1}{2} \left[\frac{x - x_{p_i}}{\sigma_{x,a}} \right]^2 \right] \Delta x_i \qquad (V.107)$$

and for large N,

$$c_c'(x) = \frac{1}{\sqrt{2\pi}} \int_0^{\infty} \frac{c_c(\xi)}{\sigma_{x,a}(\xi - \xi_0)} \exp\left[-\frac{1}{2} \left[\frac{x - \xi}{\sigma_{x,a}(\xi - \xi_0)} \right]^2 \right] d\xi \qquad \text{(V.108)}$$

The corrected centerline concentration c_c' is used in the assumed profiles in place of c_c, along with the distribution parameters S_y, S_z, and b.

VI. CONCLUSIONS AND RECOMMENDATIONS

DEGADIS was designed to model the atmospheric dispersion of ground-level, area-source dense gas (or aerosol) clouds released with zero (initial) momentum into an atmospheric boundary layer over flat, level terrain. DEGADIS describes the dispersion processes which accompany the ensuing gravity-driven flow and entrainment of the gas into the atmospheric boundary layer.

A jet-plume model has been interfaced with DEGADIS to provide for prediction of the trajectory and dilution of vertically oriented gas or aerosol jets. When the jet plume returns to ground level, DEGADIS predicts the ensuing ground-level plume dispersion. The jet-plume model provides for

- automatic adjustment of integration step-size (using the Runge-Kutta-Gill method as in DEGADIS),
- elliptical plume shape (cross-section), with air entrainment specified consistent with the Pasquill-Gifford plume dispersion coefficient representation of atmospheric turbulent entrainment,
- application to scenarios where the plume returns to ground level or remains aloft, and
- ground reflection when the plume (lower) boundary reaches ground level.

It is recommended that the following limitations and cautions be observed when using the jet-plume and DEGADIS models.

- The jet-plume model presently provides only for vertically oriented releases.
- Both models assume an unobstructed atmospheric flow field. The jet-plume model assumes a logarithmic wind profile, and the DEGADIS model assumes a power law wind profile which is consistent with the logarithmic wind profile. Application of the models should be limited to releases where the depth of the dispersing layer is much greater than the height of the surface roughness elements.
- Averaging time can be user-specified. There are three important time scales for the typical dispersion application: the averaging time input to the model (t_{av}), the time scale assumed for specification of the concentration/hazard relation (t_{haz}), and the time required for the contaminant material to be taken up by

the atmosphere (t_{rel}). The averaging time t_{av} influences the rate of lateral spread (dispersion) due to atmospheric turbulence (δ_y). For an elevated release which does not return to the ground, t_{rel} is the duration of the release. For a transient ground-level release or for an elevated release which returns to the ground, t_{rel} is the duration of the secondary source blanket in DEGADIS. For a steady-state release (large t_{rel}), t_{av} should be set to t_{haz}. (For example, if t_{haz} is based on toxicological data for one hour exposure, then $t_{haz} = t_{av} = 3600$ s.) For a transient release, t_{av} should be set to the minimum of t_{haz} or t_{rel}. If $t_{haz} \leq t_{rel}$, $t_{av} = t_{haz}$. If $t_{rel} < t_{haz}$, $t_{av} = t_{rel}$, and the concentration time history at a given position should be averaged over t_{haz} to determine the hazard.

APPENDIX A

MODEL APPLICATION ON VAX/VMS

DEGADIS Version 2.1 (including the jet/plume front-end model) was developed under VAX/VMS V3.5 and VAX-11 Fortran V3.5; there should be no installation difficulty for VAX/VMS V4.0 or later.

Installation

The directory which contains the Fortran source code for DEGADIS must be equivalenced with the logical name SYS$DEGADIS:. If the full directory specification is DQA0:[DEGADIS_V21], issue the VAX/VMS command:

```
$ ASSIGN DQA0:[DEGADIS_V21] SYS$DEGADIS:
```

with either the /PROCESS, /GROUP, or /SYSTEM qualifier (/SYSTEM is recommended). Once this assignment is made, the files must be compiled and linked to form DEGADISIN, DEGADIS1, DEGADIS2, DEGADIS3, DEGADIS4, and SDEGADIS2; the VMS command procedure BUILD.COM performs these tasks. The process which compiles and links DEGADIS must have READ, WRITE, and EXECUTE access privileges to SYS$DEGADIS while only READ and EXECUTE access privileges are needed to execute the existing models.

Considerations for Installation other than VAX/VMS

There are two types of problems which may occur when attempting to install DEGADIS on a different computer or operating system. The first is due to the use of non-standard ANSI Fortran 77 language elements. The second is due to the use of external VAX/VMS routines in DEGADIS.

The following VAX-11 Fortran extensions have been used in DEGADIS:

(*) In-line comments--An exclamation mark (!) is used to include comments at the end of a valid statement.

(*) Special characters--The underscore (_) is used in variable names.

(*) DO loops--DO loops are used with the structure:

```
DO v = e1,e2[,e3]
 .
 .
 .
END DO
```

where v is a variable name and e1, e2, and e3 are numeric expressions. The numeric expressions have the standard Fortran 77 meaning.

(*) INCLUDE statements--INCLUDE statements simply allow other source files to be inserted in the routine being compiled at this point in the source. The system table '($SSDEF)' is used to check the status or returning system routines.

(*) OPEN keyword NAME--The OPEN keyword NAME specifies the file name to be opened.

(*) Fortran descriptors--The Q descriptor obtains the integer number of characters remaining in the input record during a READ operation. The dollar sign ($) descriptor suppresses the carriage return at the end of a line on output.

(*) Continuation lines--Continuation lines have been expressed by using either a nonblank character in column 6 or by beginning the line with a tab and a number in the next column.

(*) Concatenation of character strings--Character strings are concatenated using two slashes (//).

The following VAX/VMS subroutines have been used in DEGADIS:

(*) SECNDS
TIME = SECNDS(TIME0)
SECNDS returns to TIME the difference between the number of seconds after midnight on the system clock and the value of TIME0.

(*) LIB$DATE_TIME
ISTAT = LIB$DATE_TIME (STRING)
LIB$DATE_TIME returns a 24-character ASCII string with the system date and time. ISTAT is an integer variable which accepts the return status.

(*) LIB$DO_COMMAND
ISTAT = LIB$DO_COMMAND (STRING)
LIB$DO_COMMAND issues the command STRING (a character string) to VAX/VMS. If the command is not issued, ISTAT contains the failure code. If the command is issued, the calling process is terminated.

Model Implementation

The (combined) jet/plume (JETPLU) and DEGADIS models consist of nine separate programs:

- JETPLU_IN is the file-based input module which defines the simulation.
- JETPLU describes the trajectory and dilution of the vertically oriented jet release.
- DEGBRIDGE is an interface program which takes the output from JETPLU (if where the jet/plume returns to ground level) and provides appropriate input to DEGADIS.

- DEGADISIN is the interactive input module which defines DEGADIS-only simulation.
- DEGADIS1 determines α and describes the gas source for transient and steady-state releases.
- DEGADIS2 describes the pseudosteady-state downwind dispersion of the released gas.
- DEGADIS3 sorts the results of DEGADIS2 for a transient release at given times.
- DEGADIS4 sorts the results of DEGADIS2 for a transient release at given positions.
- SDEGADIS2 describes the steady-state downwind dispersion of the released gas.

Steady-state releases are simulated by executing JETPLU, DEGBRIDGE, DEGADIS1, and SDEGADIS2; time-limited (transient) releases are simulated by executing JETPLU, DEGBRIDGE, DEGADIS1, DEGADIS2, and DEGADIS3.

The JETPLU DEGADIS model uses three types of input information
- VAX/VMS command procedure for execution
- simulation definition
- numerical parameters.

The VAX/VMS command procedure used to execute JETPLU DEGADIS is generated by JETPLU_IN which also reads the simulation definition. DEGADIS can be run without JETPLU (for ground-level, zero momentum releases). Input to DEGADIS is made to run interactively using DEGADISIN. Example input sessions are included in Appendix B. The numerical parameters (convergence criteria, initial increments, etc.) are supplied to DEGADIS through a series of input files. Although these numerical parameters are easily changed, the user should need to change these only rarely (with the exception of the time-sort parameters which are explained later in this appendix).

VAX/VMS Command Procedures

The VAX/VMS command procedure generated by JETPLU_IN controls the execution of programs for the simulation. Program execution follows one of two paths: (a) a transient (time-limited) release or (b) a steady-state release. JETPLU_IN, which automatically generates the appropriate command procedure, requires a simulation name be specified. The simulation name must be a valid VAX/VMS file name without a file extension and is designated RUN_NAME. JETPLU and DEGADIS will use this file name with standard extensions for input, interprocess communication, and output. Figures A.1 and A.2 show example VAX/VMS command procedures created by JETPLU_IN for the run names TEST_S and TEST for steady-state and transient releases, respectively. The directory which contains the executable images has been assigned the system logical name SYS$DEGADIS. The COPY/LOG command copies a file

from the first argument to the second argument, and the RUN command executes the specified image. These steps may also be carried out by issuing the commands at a terminal.

```
$ assign test_s.ino for001
$ assign test_s.out for003
$ assign test_s.ind for002
$ run sys$degadis:jetplu
$ deassign for001
$ deassign for002
$ deassign for003
$ run sys$degadis:degbridge
test_s
$ copy/log SYS$DEGADIS:example.er1 test_s.er1
$ copy/log SYS$DEGADIS:example.er2 test_s.er2
$ run SYS$DEGADIS:DEGADIS1
test_s
$ run SYS$DEGADIS:SDEGADIS2
test_s
$ copy/log test_s.out + test_s.scl + test_s.sr3 -
  test_s.lis
```

Figure A.1. Example DEGADIS Command Procedure on VAX/VMS for a Steady-State Simulation Named TEST_S.

```
$ assign test.ino for001
$ assign test.out for003
$ assign test.ind for002
$ run sys$degadis:jetplu
$ deassign for001
$ deassign for002
$ deassign for003
$ run sys$degadis:degbridge
test
$ copy/log SYS$DEGADIS:example.er1 test.er1
$ copy/log SYS$DEGADIS:example.er2 test.er2
$ copy/log SYS$DEGADIS:example.er3 test.er3
$ run SYS$DEGADIS:DEGADIS1
test
$ run SYS$DEGADIS:DEGADIS2
test
$ run SYS$DEGADIS:DEGADIS3
TEST
$ copy/log test.out + test.sc1 + test.sr3 -
  test.lis
```

Figure A.2. Example DEGADIS Command Procedure on VAX/VMS for a Transient Simulation Named Test.

Simulation Definition

JETPLU_IN specifies information about the ambient wind field, the properties of the released material, and details of the release.

The input uses free-formatted files; a value for each parameter must be specified in the input file even if it has no meaning for the simulation at hand. This form of input allows the user to ignore spacing in the input file. Numbers on a particular line can be separated by commas, spaces, or tabs. Comments may also be included at the end of any line in the input file as long as all required values are given before any comments are included. Lines which are only comments are allowed only after all required values have been specified. (Sample input files are included in Appendix B.)

The ambient wind field is characterized by a known velocity u_0 at a given height z_0, a surface roughness z_R, and the Pasquill stability class or Monin-Obukhov length. The Pasquill stability class is required to estimate values of the lateral, vertical, and along-wind similarity coefficients. If specified, the Monin-Obukhov length λ is required to calculate the friction velocity u_*. In addition to these specifications, the ambient temperature, pressure, and humidity must be specified.

The contaminant properties are used by the model to fix the mixture density from the contaminant concentration. In the model, there are three possible ways to simulate the mixture density:

Case 1: Treat the contaminant as an ideal gas and allow for condensation of ambient humidity. This is accomplished by setting <NDEN>=0. In DEGADIS, ground-to-cloud heat transfer can either by included (<INDHT>=1) or precluded (<INDHT>=0). The contaminant heat capacity is determined by <CPK> and <CPP> using

$$C_{p_c}(T) = (MW_c)^{-1}\left[3.33 \times 10^4 + q_1\left[\frac{T^{p_1} - T_0^{p_1}}{T - T_0}\right]\right] \qquad (A.1)$$

where <CPK> is denoted by q_1 and <CPP> is denoted by p_1. If a constant heat capacity is desired, set <CPP> to 0. and <CPK> to the desired heat capacity (in J/kg K).

Case 2: Treat the contaminant as an ideal gas and do not allow for condensation of ambient humidity. In this case, ground-to-cloud heat transfer in DEGADIS is not allowed, and $(\rho - \rho_a)/c$ is assumed constant. This is accomplished by setting <NDEN>=-1. Values input for <INDHT>, <CPK>, and <CPP> are ignored.

Case 3: Estimate the contaminant/air mixture density as a function of contaminant concentration based on a user-supplied estimate. Ordered triples of the contaminant mole fraction, the contaminant concentration (kg/m^3), and the contaminant/air mixture density (kg/m^3) are input to the model. This is accomplished by setting <NDEN> equal to the number of triples. In the input file, the ordered triples (starting with pure air) are input on the next NDEN lines immediately following the line for <NDEN>. Values input for <INDHT>, <CPK>, <CPP>, and <TEMJET> are ignored.

The user must choose to simulate the release as time-limited (transient) or steady-state (by the specification of <TEND>), and the jet elevation and diameter must be specified.

Figure A.3 summarizes the structure of the input file RUN_NAME.IN required by JETPLU_IN. The description following is written for each of the variables in Figure A.3. After each line of input, an explanation is included. All units are SI (meters, kilograms, second) except as specified.

Figure A.3. RUN_NAME.IN Structure Required by JETPLU_IN

<TITLE1>
<TITLE2>
<TITLE3>
<TITLE4>

<TITLE1>, <TITLE2>, <TITLE3>, and <TITLE4> are four lines of up to 80 characters each of a title for this simulation.

<U0> <Z0>

<U0> (m/s) is the ambient wind velocity at <Z0> (m).

<ZR>

<ZR> is the surface roughness (m).

<INDVEL> <ISTAB> <RML>

<INDVEL> is an indicator which determines the method of calculation for the ambient velocity profile in the jet/plume model as follows:

For <INDVEL>=1, the Pasquill-Gifford stability category (in <ISTAB> using 1 for A, 2 for B, etc.) is used along with

<ZR> to determine the Monin-Obukhov length <RML>; the log velocity profile is then determined using <RML>.

For <INDVEL>=2, the Monin-Obukhov length <RML> is supplied by the user; the log velocity profile is then determined using <RML>. Note that <ISTAB> must still be specified.

<TAMB> <PAMB> <RELHUM>

<TAMB>, <PAMB>, and <RELHUM> are the ambient temperature (K), the ambient pressure (atm or N/m^2), and the relative humidity (%), respectively.

<TSURF>

<TSURF> is the surface temperature (K); if <TSURF> < 250 K, <TSURF> is set to <TAMB>.

<GASNAM>

<GASNAM> is a three-letter designation for the contaminant name. Any character string of three letters or less is valid; this is for user run identification and does not access property data.

<GASMW>

<GASMW> is the contaminant molecular weight (kg/kmole).

<AVTIME>

<AVTIME> is the averaging time (s). This parameter is used to estimate the value of <DELTAY>.

<TEMJET>

<TEMJET> is the temperature of the released contaminant (K).

<GASUL> <GASLL> <ZLL>

<GASUL> and <GASLL> are the concentrations to be used for estimating contours for an upper and lower concentration level in DEGADIS. The calculations are made for the elevation <ZLL>. Note that the JETPLU/DEGADIS computations will be carried out to <GASLL>/2.

<INDHT> <CPK> <CPP>

<INDHT> is used to include heat transfer in the DEGADIS computations. Heat transfer is not included for <INDHT>=0. For <INDHT>=1, heat transfer is included, and the heat transfer coefficient is calculated by DEGADIS. <CPP> and <CPK> are used to calculate the heat capacity as a function of temperature according to the correlation included in DEGADIS. If a constant heat capacity is desired, set <CPP> to 0. and <CPK> to the desired heat capacity (J/kg K).

<NDEN>

<NDEN> is used to specify the contaminant density profile. There are three cases for <NDEN>:

<NDEN> = -1; The simulation treats the contaminant as if it were an ideal gas with a molal heat capacity equal to that of air. Water condensation effects are ignored (equivalent to an "isothermal" release in DEGADIS).

<NDEN> = 0; The simulation treats the contaminant as if it were an ideal gas with the heat capacity indicated by <CPK> and <CPP>. Water condensation effects are taken into account as appropriate (equivalent to a nonisothermal release in DEGADIS).

<NDEN> > 0; <NDEN> specifies the number of triples which follow in the next <NDEN> lines. The triples are used to specify the contaminant concentration as a function of density based on adiabatic mixing with ambient air. The ordered triples represent (in order):

(1) the contaminant mole fraction
(2) the contaminant concentration (kg contam/m^3 mix)
(3) the mixture density (kg mixture/m^3 mixture).

The ordered triples must go from pure air to pure contaminant (equivalent to an "isothermal" release in DEGADIS).

<ERATE>

<ERATE> is the mass evolution (release) rate (kg/s).

<ELEJET> <DIAJET>

<ELEJET> is the initial jet elevation (m), and <DIAJET> is the initial jet diameter (m).

<TEND>

<TEND> is the duration of the primary release (s). For steady-state releases, set <TEND> to 0.; to run the jet/plume model only, set <TEND> to a negative number.

<DISTMX>

<DISTMX> is the maximum distance between output points in the JETPLU output (m).

DEGBRIDGE takes the output from the jet/plume model and creates the file necessary for DEGADIS to complete the simulation.

Input Module--DEGADISIN

DEGADISIN is the optional interactive input module which defines a DEGADIS simulation; DEGADISIN is composed of two subroutines (Figure A.4):

(*) DEGADISIN contains the program overhead and generates the command file RUN_NAME.COM which can be used to control simulation execution (D-38).

(*) IOT contains the interactive question-and-answer sequence which defines the simulation; IOT also creates the file RUN_NAME.INP (D-76).

An example of a DEGADISIN query sequence is included in Appendix B. As this information is gathered, it is written to the file RUN_NAME.INP (Figure A.5). Once DEGADISIN is completed, RUN_NAME.INP may be edited to correct minor input mistakes. If major revisions are necessary, the recommended practice is to execute DEGADISIN again.

Once the information required by DEGADISIN has been entered properly, DEGADIS may be executed using the command procedure generated by DEGADISIN under the file name RUN_NAME.COM. If DEGADIS is not to be run using this command file, the user must enter the simulation name (RUN_NAME) after each of the programs are begun. (In this case, the user must also provide copies of the numerical parameter files.)

Figure A.5. Structure for Free-Formatted RUN_NAME.INP File.

Source Module--DEGADIS1

DEGADIS1 estimates values for the friction velocity and ambient wind profile power α and characterizes the primary gas source for the remainder of the model; DEGADIS1 is composed of the following subroutines (Figure A.6):

(*) AFGEN — linearly interpolates between a pair of points based on a list of supplied values (D-3).

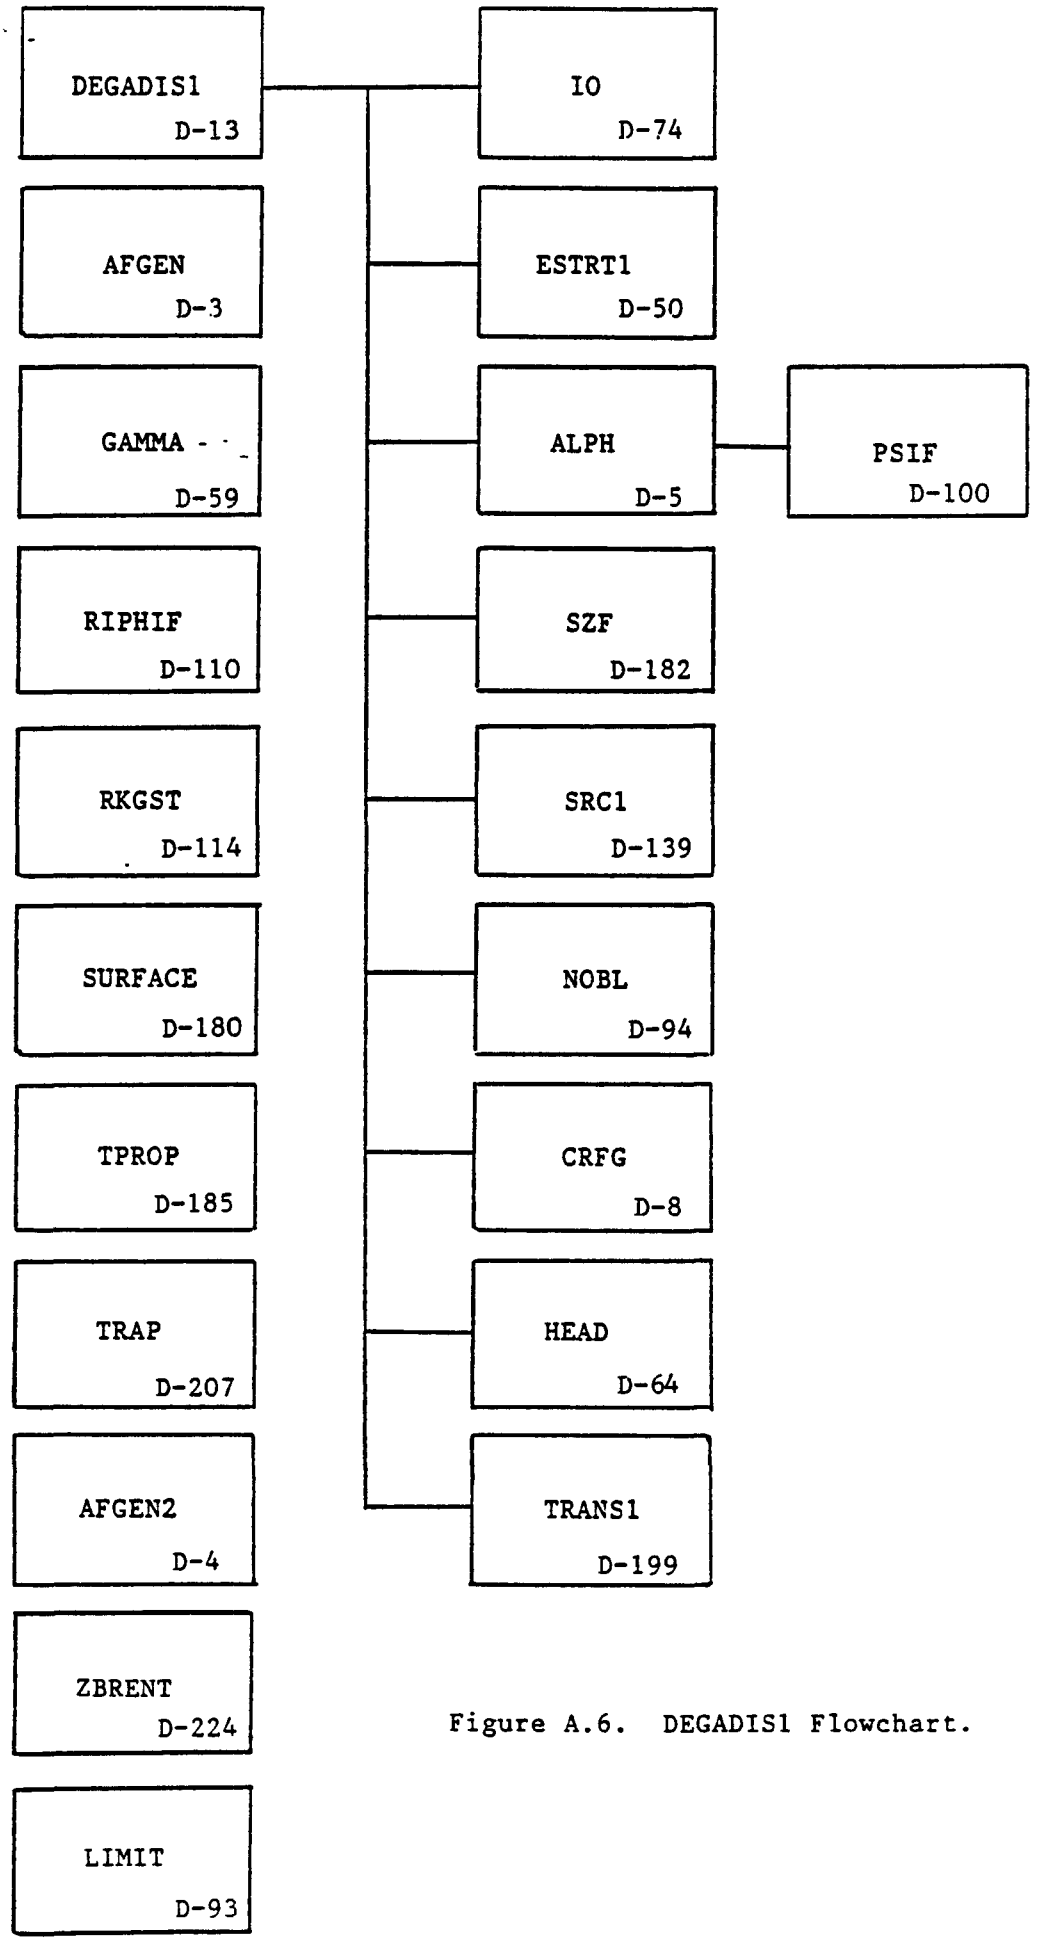

Figure A.6. DEGADIS1 Flowchart.

(*) AFGEN2	linearly interpolates between a pair of points based on a list of supplied values (D-4).
(*) ALPH	estimates the ambient wind profile power α by minimizing the integral of the difference between an ambient logarithmic velocity profile and the assumed power law velocity profile (D-5).
(*) CRFG	creates a table of calculated values which will describe the secondary gas source for the downwind dispersion calculations (D-8).
(*) DEGADIS1	contains the program overhead and sequentially calls the routines required to estimate the ambient wind profile power α and to characterize the primary gas source (D-14).
(*) ESTRT1	recovers the numerical parameters contained in the file RUN_NAME.ER1 (D-50).
(*) GAMMA	calculates the gamma function of the argument (I.e. $\Gamma(x)$) (D-59).
(*) HEAD	writes a formatted output heading to the file RUN_NAME.SCL (D-64).
(*) IO	recovers the simulation definition contained in RUN_NAME.INP (D-74).
(*) LIMIT	establishes the limit for ZBRENT (D-93).
(*) NOBL	estimates gas source behavior when no gas blanket is present (D-94).
(*) PSIF	calculates the ψ function in the logarithmic velocity profile (D-100).
(*) RIPHIF	calculates the Richardson number and the values of $\phi(Ri_*)$ and $\hat{\phi}(Ri_*)$ (D-110).
(*) RKGST	performs numerical integration of a specified system of equations using a variable-step, modified fourth-order Runge-Kutta method (D-114).
(*) SCR1	contains the ordinary differential equations which describe the gas blanket formed as a result of the primary gas source (D-139).

(*) SURFACE — estimates heat and water transfer rates across the bottom surface of the gas layer (D-180).

(*) SZF — estimates the value of S_Z if the primary source can just form a gas blanket over the source (D-182).

(*) TPROP — is a series of utility routines which estimate the thermodynamic properties of a given gas mixture (D-185).

(*) TRANS1 — writes the information to continue the next simulation step to the file RUN_NAME.TR2 (D-199).

(*) TRAP — is a utility included for program diagnostics (D-207).

(*) ZBRENT — finds the bracketed root of an equation using Brent's method (D-224).

As input, DEGADIS1 requires two files:

(*) RUN_NAME.ER1 — contains various numerical parameters. For most simulations, a copy of the SYS$DEGADIS:EXAMPLE.ER1 file will be adequate. A copy of SYS$DEGADIS:EXAMPLE.ER1 is included in Figure A.7.

(*) RUN_NAME.INP — contains the simulation definition as discussed in Appendix B (Figure A.5).

As output, DEGADIS1 generates the following files:

(*) RUN_NAME.SCD — contains the calculated values which describe the secondary gas source. It is generated by SRC1 and NOBL and is then read by CRFG; it is a temporary file.

(*) RUN_NAME.SCL — is the listed output which describes the input information for the simulation and the calculated secondary gas source. It is written by HEAD and CRFG.

(*) RUN_NAME.TR2 — contains the information to continue the next simulation step.

Figure A.7. (concluded)

Pseudosteady-State Module--DEGADIS2

DEGADIS2 performs the downwind dispersion portion of the calculation for each of several observers released successively over the transient source described by DEGADIS1. (Note that the routines INCGAMMA, GAMMA, and SERIES are linked in DEGADIS2 but never are called in DEGADIS2.) DEGADIS2 is composed of the following subroutines (Figure A.8):

(*) AFGEN	linearly interpolates between a pair of points based on a list of supplied values (D-3).
(*) AFGEN2	linearly interpolates between a pair of points based on a list of supplied values (D-4).
(*) DEGADIS2	contains the program overhead and sequentially calls the routines to recover the information generated in DEGADIS1, recover the numerical parameter file RUN_NAME.ER2, and perform the simulation (D-23).
(*) ESTRT2	recovers the numerical parameters contained in the file RUN_NAME.ER2, particularly the number of observers NOBS (D-54).
(*) LIMIT	establishes the limit for ZBRENT (D-93).
(*) OB	contains the ordinary differential equations which average the gas source for each observer (D-97).
(*) PSS	contains the ordinary differential equations which describe the portion of the downwind dispersion calculation when b > 0 (D-100).
(*) PSSOUT	governs the output of calculated points to the file RUN_NAME.PSD when PSS is active (D-104).
(*) RIPHIF	is a series of utilities which calculates the Richardson number and the value of ϕ(Ri) (D-110).
(*) RKGST	performs numerical integration of a specified system of equations using a modified fourth-order Runge-Kutta method (D-114).
(*) SSG	contains the ordinary differential equations which describe the portion of the downwind dispersion calculation when b = 0 (D-152).
(*) SSGOUT	governs the output of calculated points to the file RUN_NAME.PSD when SSG is active (D-155).

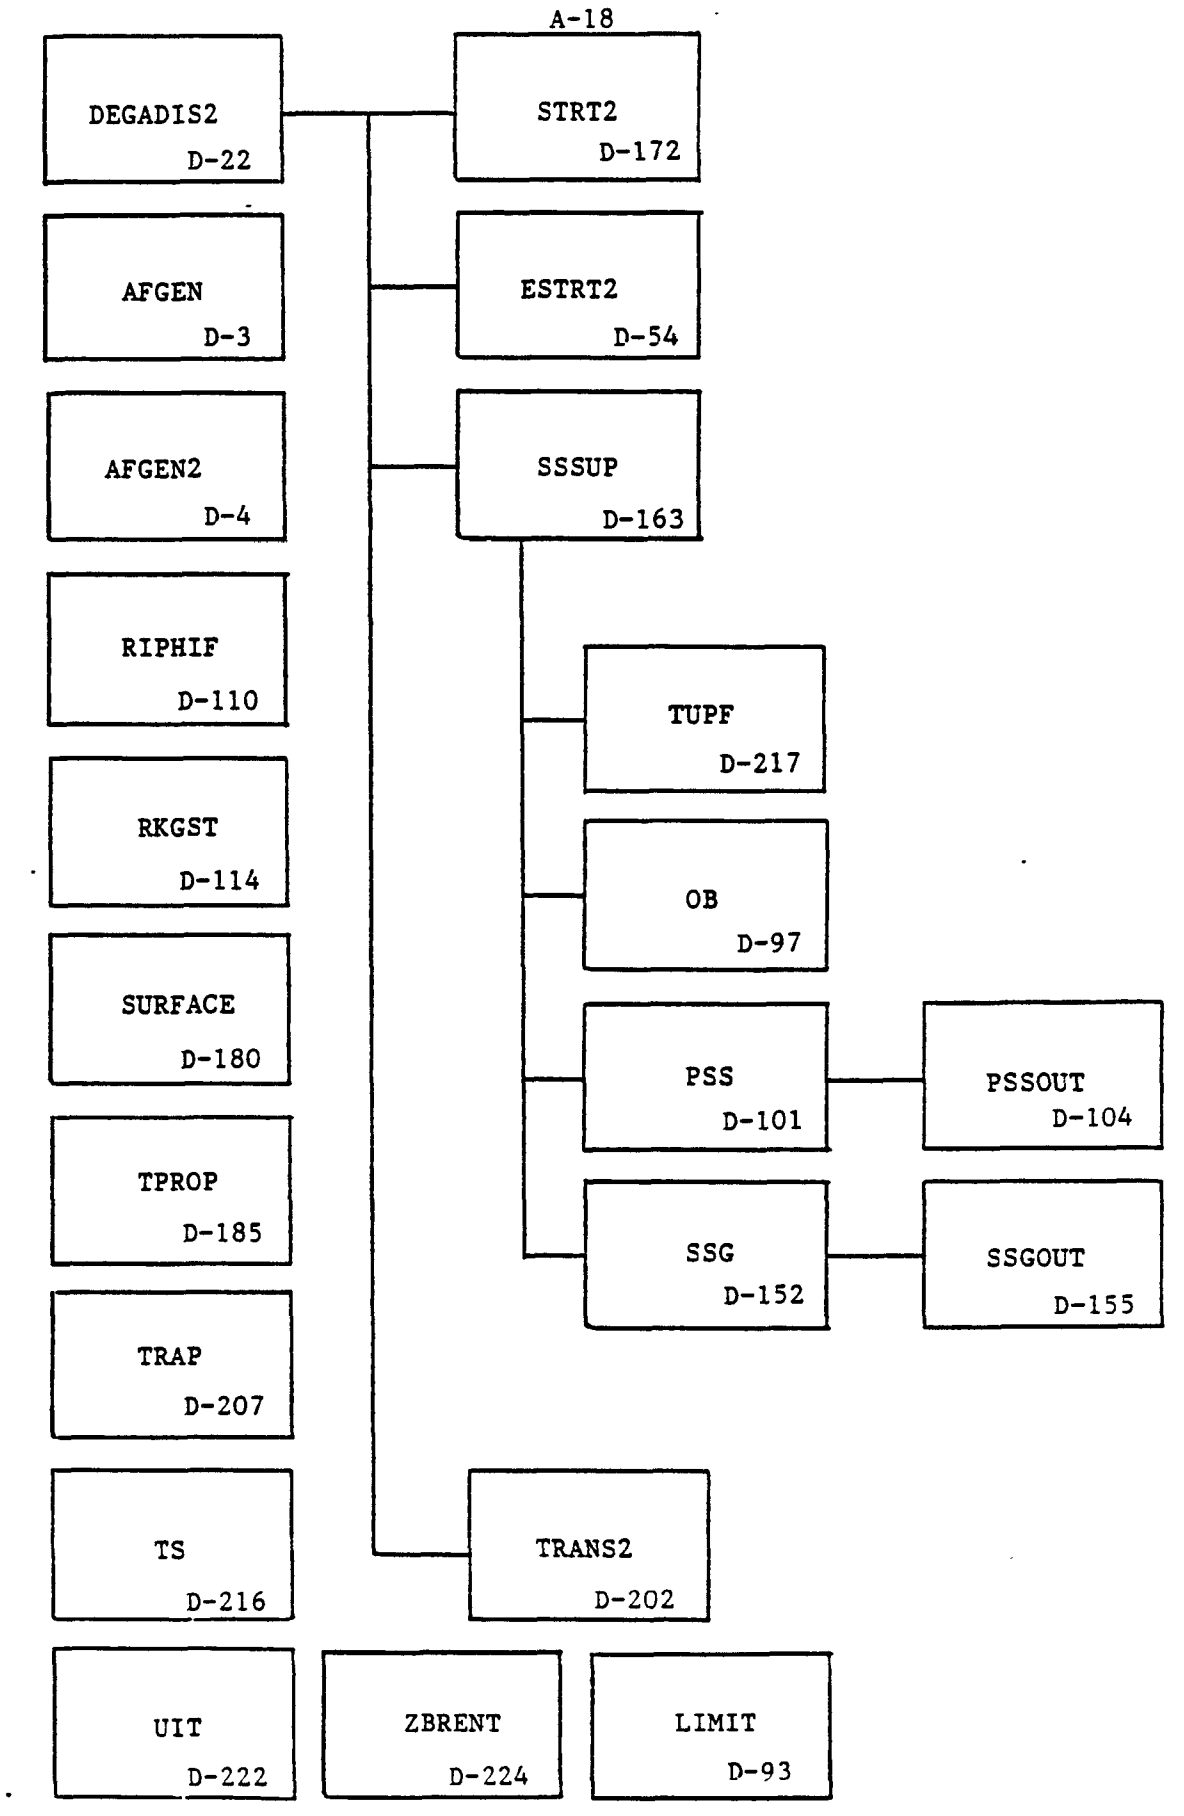

Figure A.8. DEGADIS2 Flowchart.

(*) SSSUP — is a supervisor routine which controls the averaging of the source for each observer, the portion of the downwind dispersion calculation when b > 0, and the portion of the downwind dispersion calculation when b = 0 (D-163).

(*) STRT2 — recovers the information generated in DEGADIS1 contained in the file RUN_NAME.TR2 (D-172).

(*) SURFACE — estimates heat and water transfer rates across the bottom surface of the gas layer (D-180).

(*) TPROP — is a series of utility routines which estimates the thermodynamic properties of a given gas mixture (D-185).

(*) TRANS2 — writes the information necessary for DEGADIS3 to the file (RUN_NAME.TR3) (D-202).

(*) TRAP — is a utility included for program diagnostics (D-207).

(*) TS — calculates the time when a given observer will be at a given downwind distance (D-216).

(*) TUPF — contains the routines which determine the intersection of the upwind/downwind edge of the secondary gas source with a given observer (D-217).

(*) UIT — is a series of routines to calculate observer position and velocity as a function of time (D-222).

(*) ZBRENT — finds the bracketed root of an equation using Brent's method (D-224).

As input, DEGADIS2 requires two files:

(*) RUN_NAME.ER2 — contains the various numerical parameters, particularly the number of observers NOBS. For most simulations, a copy of the SYS$DEGADIS:EXAMPLE.ER2 file will be adequate. A copy of SYS$DEGADIS:EXAMPLE.ER2 is included in Figure A.9.

(*) RUN_NAME.TR2 — contains the basic simulation definition as well as calculated secondary source parameters.

DEGADIS2 generates the following output files:

(*) RUN_NAME.OBS — contains a summary of the source parameters for each observer.

Figure A.9. SYS$DEGADIS:EXAMPLE.ER2 Listing.

(*) RUN_NAME.PSD contains the calculated downwind dispersion parameters for each observer. DEGADIS3 and DEGADIS4 sort this information to determine the downwind concentration profiles as a function of position and time.

(*) RUN_NAME.TR3 contains the simulation definition and the number of each record type written to RUN_NAME.PSD.

Time Sort Modules--DEGADIS3 and DEGADIS4

DEGADIS3 sorts the downwind dispersion calculation for each of several observers for concentration information at several given times; the along-wind dispersion correction is then applied as desired. DEGADIS3 uses the following subroutines (Figure A.10).

(*) DEGADIS3 contains the program overhead and sequentially calls the routines to recover the information generated in DEGADIS2, recover the numerical parameter file RUN_NAME.ER3, sort and apply the along-wind dispersion correction to the results of DEGADIS2, and output the results (D-28).

(*) ESTRT3 recovers the numerical parameters contained in the file RUN_NAME.ER3, particularly the time sort parameters (D-58).

(*) GAMMA calculates the gamma function of the argument (i.e. $\Gamma(x)$) D-59).

(*) GETTIM sets the default time sort parameters as needed (D-61).

(*) INCGAMMA calculates the incomplete gamma function of the two arguments (D-70).

(*) LIMIT establishes the limit for ZBRENT (D-93).

(*) SERIES evaluates a series needed to estimate the mass of gas above a given concentration level (D-130).

(*) SORTS recovers the information in RUN_NAME.PSD and arranges the information according to the time sort parameters in the file RUN_NAME.ER3 (D-131).

(*) SORTS1 applies the along-wind dispersion correction to the time-sorted information (D-134).

(*) SRTOUT generates the formatted output file RUN_NAME.SR3 (D-148).

(*) STRT3 recovers the information generated in DEGADIS2 contained in the file RUN_NAME.TR3 (D-178).

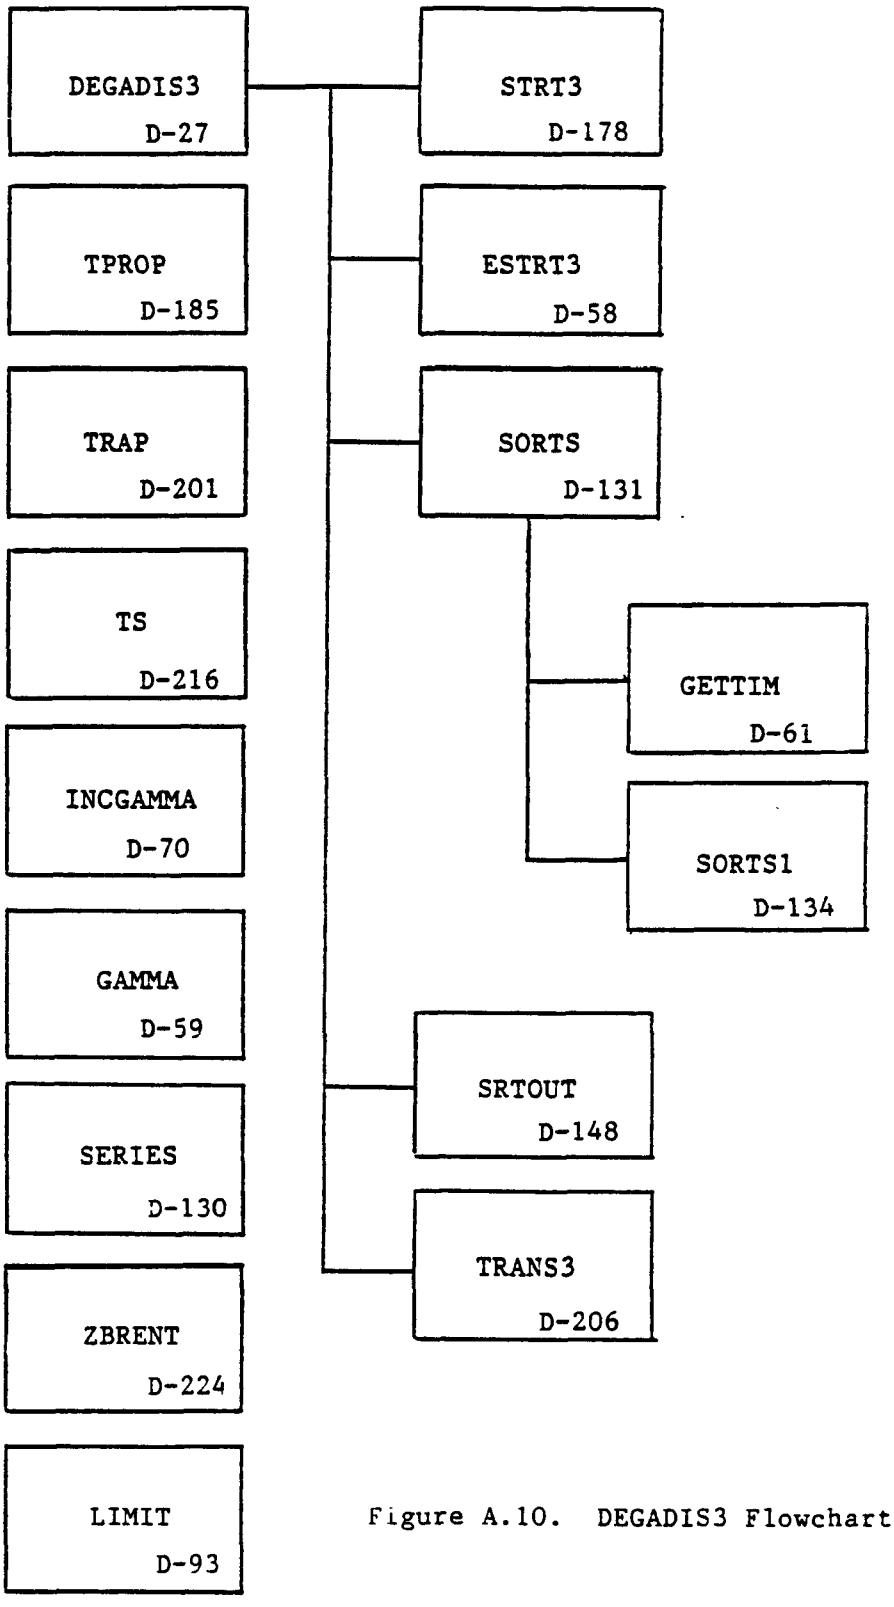

Figure A.10. DEGADIS3 Flowchart.

(*) TPROP — is a series of utility routines which estimate the thermodynamic properties of a given gas mixture (D-894).

(*) TRANS3 — writes RUN_NAME.TR4 which contains the necessary information to recover the other output files for this simulation (D-206).

(*) TRAP — is a utility included for program diagnostics (D-207).

(*) TS — calculates the time when a given observer will be at a given downwind distance (D-216).

(*) ZBRENT — finds the bracketed root of an equation using Brent's method (D-224).

As input, DEGADIS3 requires three files:

(*) RUN_NAME.ER3 — contains various numerical parameters including the time sort parameters and the flag which dictates whether the along-wind dispersion correction is applied. A copy of SYS$DEGADIS:EXAMPLE.ER3 file uses the default time sort parameters and includes the along-wind dispersion correction which should apply for most simulations. A copy of SYS$DEGADIS:EXAMPLE.ER3 is included in Figure A.11.

(*) RUN_NAME.PSD — contains the calculated downwind dispersion parameters for each observer. DEGADIS3 sorts this information to determine the downwind concentration profiles as a function of position at a given time.

(*) RUN_NAME.TR3 — contains the number of each record type written to RUN_NAME.PSD as well as the simulation definition.

As output, DEGADIS3 generates two new files:

(*) RUN_NAME.SR3 — is the formatted output list of the time-sorted concentration parameters. Concentration contours are generated for the specified upper and lower levels of concern at the specified height entered in DEGADISIN or JETPLU_IN.

(*) RUN_NAME.TR4 — contains the necessary information to recover the other output files to facilitate further processing.

Figure A.11. SYS$DEGADIS:EXAMPLE.ER3 Listing.

DEAGDIS4 sorts the downwind dispersion calculation for each of several observers for concentration information at several given positions; the along-wind dispersion correction is then applied as desired. DEGADIS4 uses the following subroutines (Figure A.12):

(*) DEGADIS4 — contains the program overhead and sequentially calls the routines to recover the information generated in DEGADIS2, recover the numerical parameter file RUN_NAME.ER3, sort and apply the along-wind dispersion correction to the results of DEGADIS2, and output the results (D-33).

(*) DOSOUT — generates the formatted output file RUN_NAME.SR4 (D-45).

(*) ESTRT3 — recovers the numerical parameters contained in the file RUN_NAME.ER3, particularly whether the x-direction dispersion correction is to be applied (D-58).

(*) GAMMA — calculates the gamma function of the argument (i.e. $\Gamma(x)$) (D-59).

(*) GETTIMDOS — sets the time sort parameters as required to output the concentration time history at the desired positions (D-63).

(*) INCGAMMA — calculates the incomplete gamma function of the two arguments (D-70).

(*) LIMIT — establishes the limit for ZBRENT (D-93).

(*) SERIES — evaluates a series needed to estimate the mass of gas above a given concentration level (D-130).

(*) SORTS — recovers the information in RUN_NAME.PSD and arranges the information according to the time sort parameters (D-134).

(*) SORTS1 — applies the x-direction dispersion correction to the time-sorted information (D-131)

(*) STRT3 — recovers the information generated in DEGADIS2 contained in the file RUN_NAME.TR3 (D-178).

(*) TPROP — is a series of routines which estimate the thermodynamic properties of a given gas mixture (D-185).

(*) TRANS3 — writes RUN_NAME.TR4 which contains the necessary information to recover the other output files for this simulation (D-206).

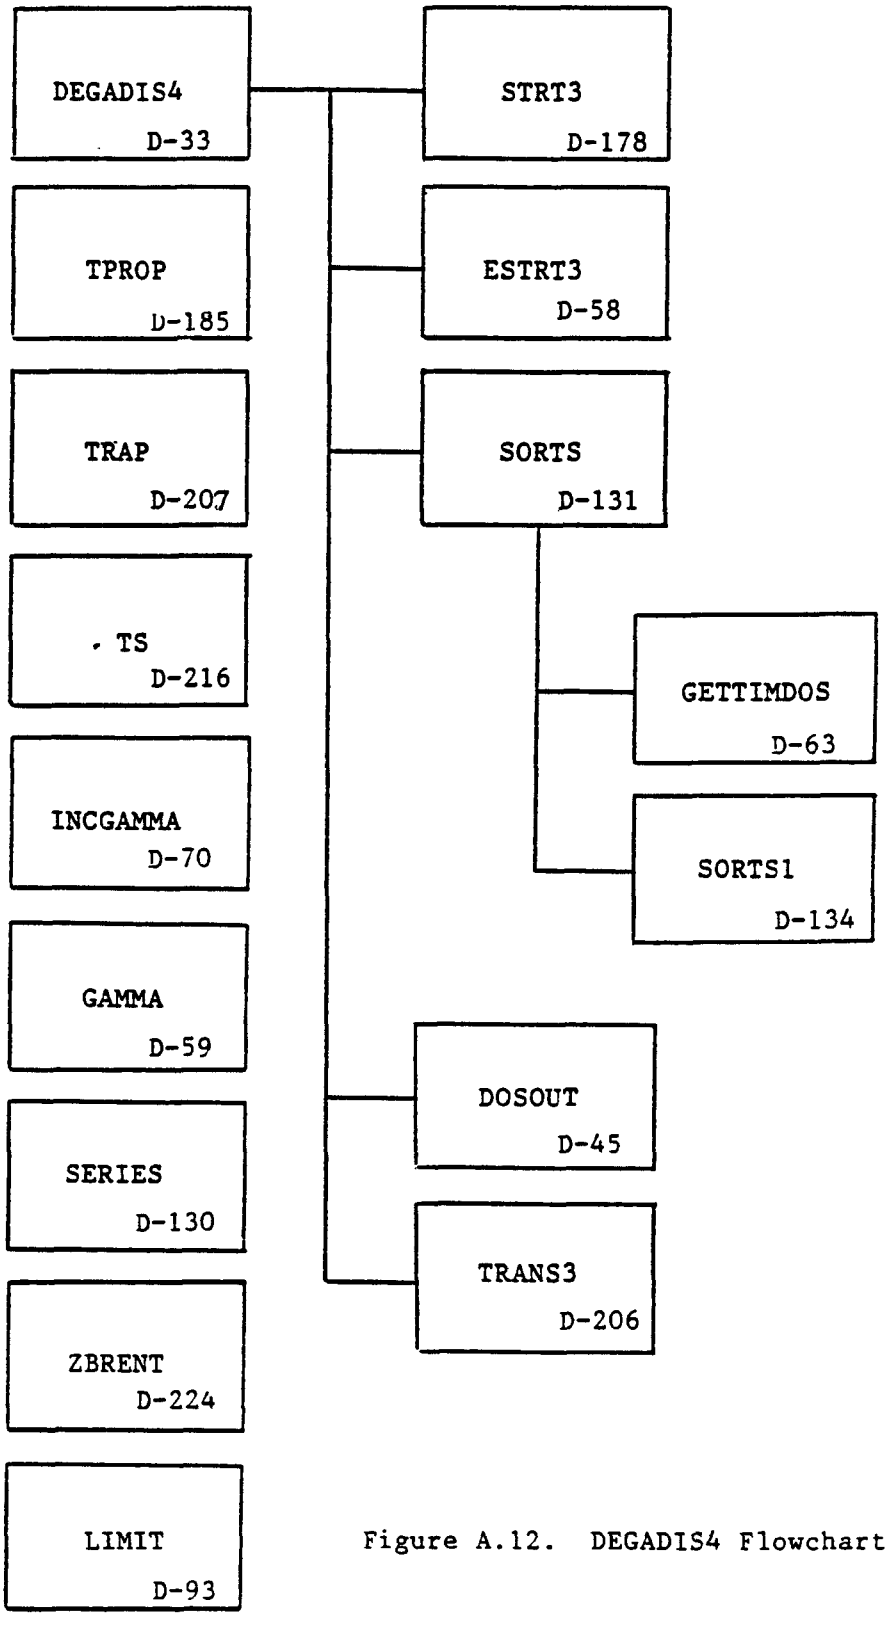

Figure A.12. DEGADIS4 Flowchart

(*) TRAP — is a utility included for program diagnostics (D-207).

(*) TS — calculates the time when a given observer will be at a given downwind distance (D-216).

(*) ZBRENT — finds the bracketed root of an equation using Brent's method (D-224).

As input, DEGADIS4 requires three files and input from the terminal:

(*) RUN_NAME.ER3 — contains the flag which dictates whether the x-direction dispersion correction is applied. A copy of SYS$DEGADIS:EXAMPLE.ER3 file includes the x-direction dispersion correction which should apply for most simulations.

(*) RUN_NAME.PSD — contains the calculated downwind dispersion parameters for each observer. DEGADIS4 sorts this information to determine the downwind concentration time histories at the desired positions.

(*) RUN_NAME.TR3 — contains the number of each record type written to RUN_NAME.PSD as well as the simulation definition.

(*) terminal input — DEGADIS4 prompts the user for the file name to be used for this run. In addition, DEGADIS4 requests the number of downwind distances (JDOS). For each downwind distance, DEGADIS4 asks for the x-position (DOSDISX(I)). Four positions are allowed for each downwind distance (DOSDISY(IJ,I)) and DOSDISZ(IJ,I) for IJ=1 to 4). If fewer than four positions are desired, negative or zero values are entered for the first position which is not desired. A summary of this input information is included in Figure A.13. Note that the same information can be put in a command file for batch processing. The same information can be put in a file which can be associated with FOR005.DAT so that a file can be used for input.

```
                                  RUN_NAME
                                  JDOS
                                  DOSDISX(I)
                                  DOSDISY(1,I),DOSDISZ(1,I)
FOR I=1 to JDOS                   DOSDISY(2,I),DOSDISZ(2,I)
                                * DOSDISY(3,I),DOSDISZ(3,I)
                                  DOSDISY(4,I),DOSDISZ(4,I)
```

Figure A.13. Structure of Input for DEGADIS4.

As output, DEGADIS4 generates two new files:

(*) RUN_NAME.SR4 is the formatted output list of the sorted concentration time histories.

(*) RUN_NAME.TR4 contains the necessary information to recover the other output files to facilitate further processing.

Steady-State Module--SDEGADIS2

SDEGADIS2 is a simplification of DEGADIS2 which uses many of the same subroutines. SDEGADIS2 performs the downwind dispersion portion of the calculation for a steady-state source described by DEGADIS1, SDEGADIS2 is composed of the following subroutines (Figure A.14):

(*) AFGEN linearly interpolates between a pair of points based on a list of supplied values (D-3).

(*) GAMMA calculates the gamma function of the argument (i.e. $\Gamma(x)$) (D-59).

(*) ESTRT2SS recovers a subset of the numerical parameters contained in the file RUN_NAME.ER2 (D-56).

(*) INCGAMMA calculates the incomplete gamma function of the two arguments (D-70).

(*) LIMIT establishes the limit for ZBRENT (D-93).

(*) PSS is the same subroutine used in DEGADIS2; it contains the ordinary differential equations which describe the downwind dispersion calculation when $b > 0$ (D-100).

(*) PSSOUTSS governs the output of calculated points to the file RUN_NAME.SR3 when PSS is active (D-107).

(*) RIPHIF calculates the Richardson number and the value of $\phi(Ri)$ (D-108).

(*) RKGST performs numerical integration of a specified system of equations using a modified fourth-order Runge-Kutta methods (D-114).

(*) SDEGADIS2 contains the program overhead and sequentially calls the routines to recover the information generated in DEGADIS1, recover the numerical parameters file RUN_NAME.ER2, and perform the steady-state simulation (D-122).

(*) SERIES evaluates a series needed to estimate the mass of gas above a given concentration level (D-130).

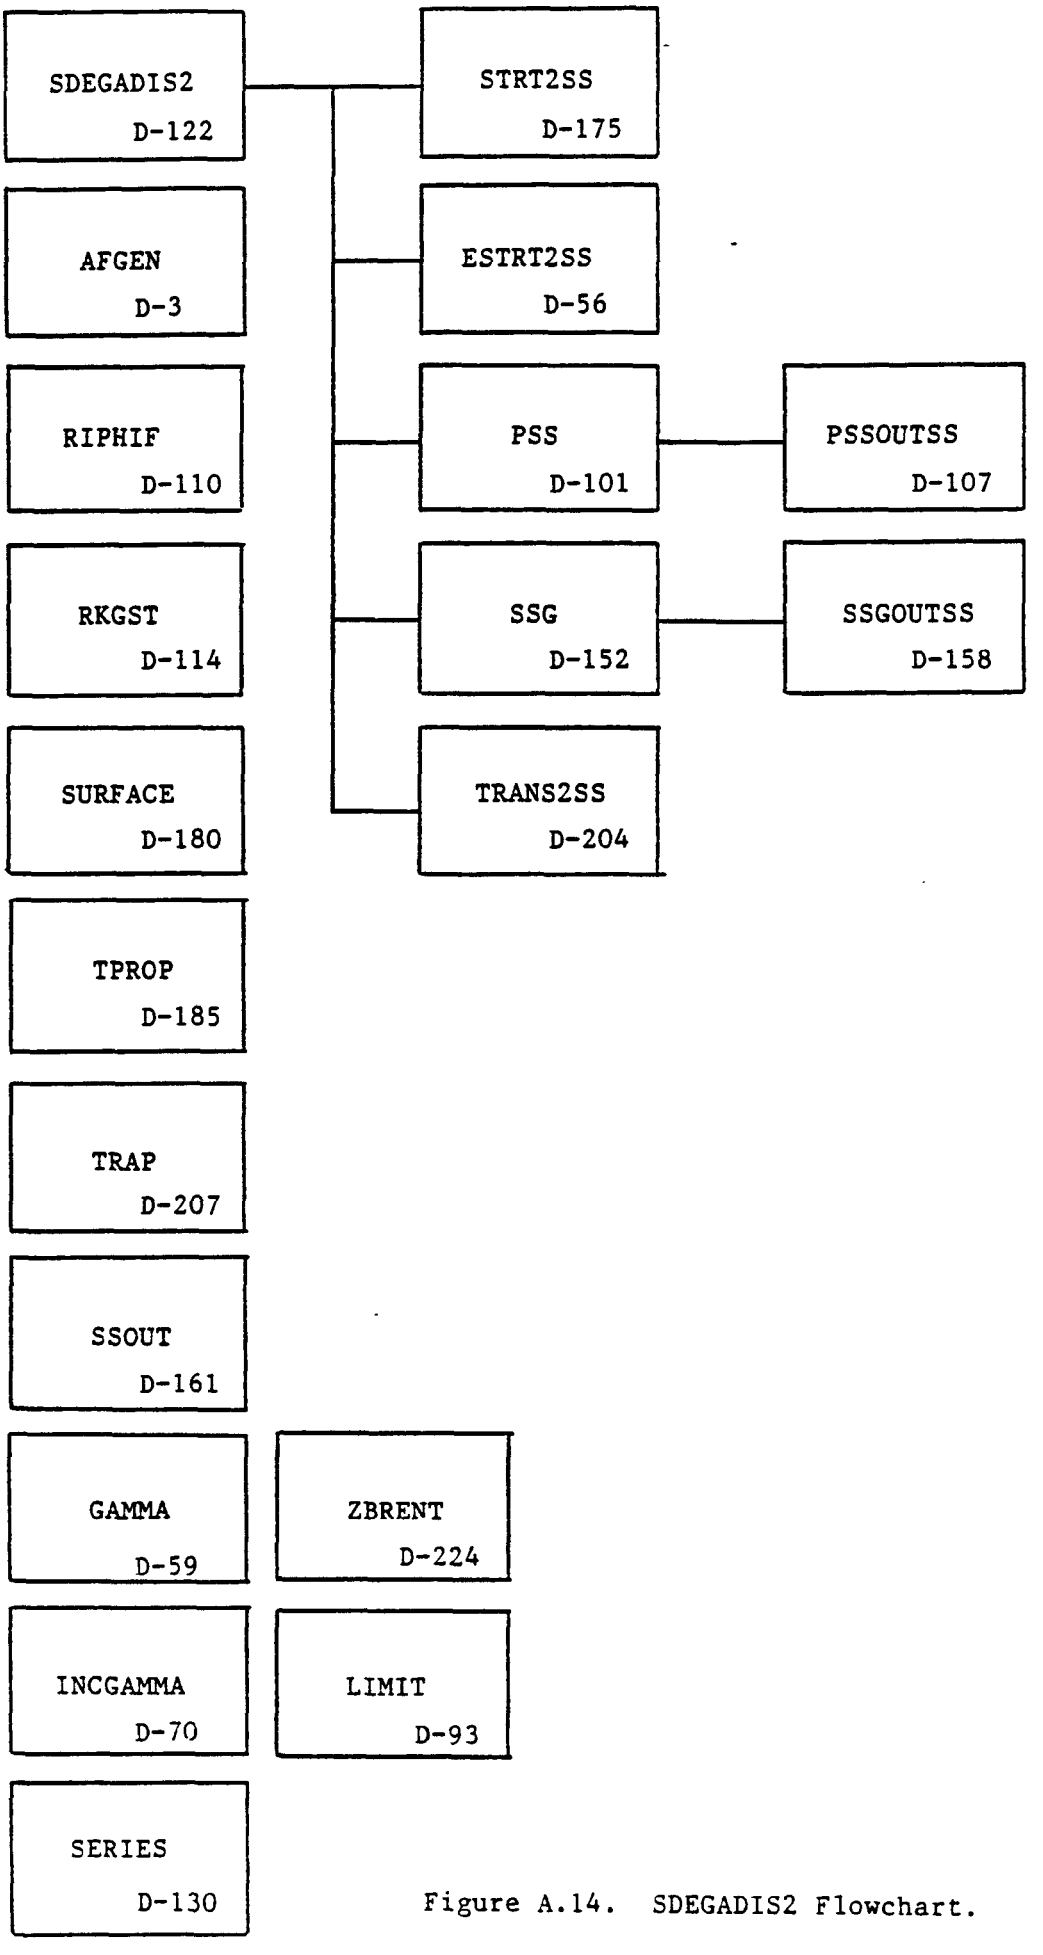

Figure A.14. SDEGADIS2 Flowchart.

(*) SSG — is the same subroutine used in DEGADIS2; it contains the ordinary differential equations which describe the downwind dispersion calculation when b = 0 (D-152).

(*) SSGOUTSS — governs the output of calculated points to the file RUN_NAME.SR3 when SSG is active (D-158).

(*) SSOUT — writes RUN_NAME.SR3 and calculates the concentration contours (D-161).

(*) STRT2SS — recovers a subset of the information generated in DEAGDIS1 contained in the file RUN_NAME.TR2 (D-175).

(*) SURFACE — estimates heat and water transfer rates across the bottom surface of the gas layer (D-180).

(*) TPROP — is a series of routines which estimate the thermodynamic properties of a given gas mixture (D-185).

(*) TRANS2SS — writes RUN_NAME.TR3 (D-204).

(*) TRAP — is a utility included for program diagnostics (D-207).

(*) ZBRENT — finds the bracketed root of an equation using Brent's method (D-224).

As input, SDEAGDIS2 requires two files:

(*) RUN_NAME.ER2 — contains various numerical parameters, the steady-state simulation typically requires only a copy of SYS$DEGADIS:EXAMPLE.ER2.

(*) RUN_NAME.TR2 — contains the basic simulation definition as well as calculated secondary source parameters; the steady-state simulation requires only part of these.

As output, SDEAGDIS2 generates the following files:

(*) RUN_NAME.SR3 — is the formatted output list of the downwind concentration parameters. Concentration contours are generated for the specified upper and lower levels of concern at the specified height entered in DEAGDISIN.

(*) RUN_NAME.TR3 — contains the necessary information to recover the other output files to facilitate further processing.

APPENDIX B

EXAMPLE MODEL INPUT AND OUTPUT

Bhopal, India, MIC Release

The example conditions shown in Table B.1 for the accidental release of methylisocyanate (MIC) on December 3, 1984, in Bhopal, India, were reported by Singh (1986). MIC was assumed released as a pure, ambient temperature gas at a steady rate of 6.72 kg/s.

Figure B.1. MIC Example Simulation Release Conditions

Mass of MIC released	40 tons
Duration of release	90 min
Vent elevation	33 m
Vent diameter	0.2 m
Wind velocity at 10 m	1.9 m/s
Atmospheric stability	E/F

The input file for a steady-state release is shown in Figure B.1. A surface roughness of 0.1 m and an averaging time of 3600 s have been specified. For the lowest concentration of interest, the lethal concentrations to 50% of laboratory animals exposed to MIC (LC_{50}) for one and two hours are about 30 and 20 ppm, respectively. The concentrations of 30 ppm (GASUL=0.00003 mole fraction) and 20 ppm (GASLL=0.00002 mole fraction) are used to determine concentration contours in DEGADIS. The steady-state condition is indicated by TEND=0.

A batch command file is shown in Figure B.2 for the simulation called EX1. (The logical symbol SYS$DEGADIS: is assigned to the directory which contains the executable image of the model.) The output of the model is in the file with the original name and extension LIS for (for this example, EX1.LIS). To run the model interactively, the lines shown in Figure B.2 can be entered at a terminal.

The program JETPLU_IN reads the input file and generates the input file to the JETPLU program; when JETPLU_IN finishes, JETPLU_IN writes the line "JETPLU_IN - beginning command file". At this point, the JETPLU program begins; several lines of output are generated showing the values of various parameters calculated by the program. When JETPLU finishes, DEGBRIDGE begins; DEGBRIDGE takes the output of JETPLU and

```
$ RUN SYS$DEGADIS:JETPLU_IN
EX1
```

Figure B.2. Example Command File Used to Simulate the EX1 Simulation.

generates the necessary input file for DEGADIS. When DEGBRIDGE finishes, the standard DEGADIS procedure begins by copying the ER1 and ER2 parameter files. DEGADIS generates several lines of output showing the values of various numerical parameters calculated by the model. Last, the model generates the LIS file from the output files of JETPLU and DEGADIS (Figure B.3).

In the JETPLU model output, columns 3-5 correspond to plume centerline position. For the specified height, columns 9 through 11 correspond to the maximum concentration and horizontal distances to the specified mole fractions, respectively. For the MIC example case, the JETPLU calculations are continued until the centerline mole fraction drops below 5 ppm (GASLL/4). The model predicts the maximum extent of the 30 and 20 ppm concentration levels to be 2500 and 4200 m, respectively.

For the UFL of 3.00000E-03 mole percent, and the LFL of 2.00000E-03 mole percent:

The mass of contaminant between the UFL and LFL is: 0.00000E+00 kg.
The mass of contaminant above the LFL is: 0.00000E+00 kg.

Figure B.3. (concluded)

Enid, Oklahoma, Ammonia Release

The model was also used to simulate an ammonia pipeline failure which occurred near Enid, Oklahoma, on May 7, 1976 (Atwood, 1976). The release occurred during early morning hours (~ 8 AM) when a bulldozer struck and ruptured an eight-inch ammonia pipeline operating at approximately 700 psi. Approximately 500 tons of ammonia were released in 4.5 hours from the ten-mile section isolated between check valves. The windspeed at the time of the accident was reported to be approximately 10 mph. The dense aerosol plume reportedly etched a parabolic-shaped scar about 6 miles long and one-half mile wide. The conditions used to simulate the release are shown in Table B.2.

Table B.2. Ammonia Example Simulation Release Conditions

Ammonia release rate	56 kg/s (twice 500 tons per 4.5 hours
Release elevation	zero (ground level)
Vent diameter	0.2 m
Wind speed (at 10 m)	4.5 m/s
Surface roughness	1 cm
Atmospheric stability	D

The input file is shown in Figure B.4. The release elevation has been set to 0.02 m (2 z_R) to avoid numerical problems. The ammonia aerosol/(humid) air mixture density shown in Figure B.5 was determined by assuming the ambient air and release ammonia aerosol mixes adiabatically (Spicer and Havens, 1988). The relationship between mixture density and ammonia concentration is input to the model with 20 ordered triples of ammonia mole fraction, ammonia concentration (kg/m^3), and ammonia/air mixture density (kg/m^3).

Figure B.6 shows the predicted 1000 ppm and 100 ppm ground-level concentration isopleths which assume one-hour averaging time for the estimation of lateral dispersion by meander. The predicted plume rise was approximately 70 meters, and the plume was predicted to return to ground level about 525 meters downwind of the release. The LIS file from the output files of JETPLU and DEGADIS is shown in Figure B.7.

For the UFL of 0.10000 mole percent, and the LFL of 1.00000E-02 mole percent:

The mass of contaminant between the UFL and LFL is: 40143. kg.
The mass of contaminant above the LFL is: 42885. kg.

Figure B.7. (concluded)

Burro Test LNG Releases

In 1980, the U.S. Department of Energy sponsored at China Lake, California, the BURRO series of LNG releases (Koopman, et al., 1982). The Burro tests were ground-level releases; their simulation does not require use of the JETPLU model. Burro 9 (Table B.3) was modeled here, both as a steady-state and transient (time-limited) release, using the DEGADIS model with interactive input via DEGADISIN.

Table B.3. Burro 9 Test Conditions

Source rate	130.0 kg/s
Source radius	22.06 m
Wind speed	6.5 m/s at 8.0 m
Atmospheric stability	C (Pasquill)
Monin-Obukhov length	-140. m
Surface roughness	2.05×10^{-4} m
Air temperature	33.4 C
Atmospheric humidity	12.5 %
Surface temperature	310 K

The source radius assumes LNG release onto water, with a constant evaporative flux of 0.085 kg/m^2 s. The input procedures for simulation of the transient release (RUN_NAME=BURRO9) and the steady-state release (RUN_NAME=BURRO9S) are very similar. Therefore, only the specification of the surface rate and extent have been included for the transient release. In the following line-by-line description of the input procedure:

(*) A line terminator (normally a carriage return) must end every line entered by the user.

(*) The file name specification RUN_NAME must satisfy system restrictions.

(*) When DEGADISIN requests the user to choose an option, responses are a single character (capital or lower case). The default responses are denoted by a capital letter inside angle brackets (e.g. <N>). When applicable, a menu of responses is included inside parentheses.

(*) For numerical responses, a comma, space, tab, or line terminator (carriage return) may separate the numbers.

(*) When a file is used as input (i.e. for the density or transient source input), DEGADISIN reads the same information from the file which would be entered at the terminal in the same order and in the same format.

Notes on Steady-State Simulation of BURRO9

(1) Begin the input procedure by execution of DEGADISIN.

(2) The file name specification must follow system restrictions. The DEGADIS model uses this file name along with various file extensions for input and output.

(3) The Title Block is used to carry any desired comments such as information on the specification of certain parameters.

(4) The wind field parameters include the wind velocity (m/s) at a specified height (m) and the surface roughness (m).

(5) The Pasquill stability class is used to generate estimates of other atmospheric parameters which follow.

(6) The averaging time is used to determine the value of δ_y (DELTAY) in the lateral dispersion coefficient specification. Changes to the values of δ_y are calculated assuming that the effect of averaging time only influences the lateral plume meander of a steady-state release.

(7) The current settings of pertinent atmospheric parameters are displayed in this list. If any of these are to be changed, the first letter of the parameter to be changed is entered. Note that the default--indicated by <N>--is No for no changes.

(8) The Monin-Obukhov length (Length in the list) is to be changed, so L is entered in response to the prompt.

(9) The list is redisplayed to verify the change and to request any further changes. The (default) response of No causes the program to go to the next question.

(10) The ambient temperature and pressure are entered.

(11) DEGADISIN calculates the ambient air density for the given input parameters.

(12) If the release is isothermal, respond "Y". A positive response causes DEGADISIN to ask for a list of concentration, density, and mole fraction points for the gas mixture. The default response is negative.

(13) If the release is simulated as adiabatic, the default negative response is chosen. For inclusion of heat transfer effects, the surface temperature and the method of calculating the heat transfer coefficient must be specified.

(14) Water transfer to the source blanket (if present) can be included in the calculation.

```
(1) RUN SYSSDEGADIS:DEGADISIN

                DEnse GAs DISpersion Model input module.

(2) Enter the simulation name : [DIR]RUNNAME BURRO9S
    INPUT MODULE -- DEGADIS MODEL

    ************************************
(3) Enter Title Block -- up to 4 lines of 80 characters
    To stop, type "//"
Steady-state simulation of BURRO 9
(4) //
    ENTER WIND PARAMETERS -- U0 (m/s), Z0 (m), and ZR(m)
    U0 -- Wind velocity at reference height Z0
    ZR -- Surface Roughness
6.5,8.,2.05E-4

(5) Enter the Pasquill stability class: (A,B,C,D,E,F) <D> C
(6) Enter the averaging time (s) for estimating DELTAY: 0.

(7) The values for the atmospheric parameters are set as follows:
DELTAY:                          0.1046
BETAY:                           0.9000
Monin-Obukhov length:           -9.3344 m
Sigma X Coefficient:             0.0200
Sigma X Power:                   1.2200
Sigma X Minimum Distance:      130.0000 m
(8) Do you wish to change any of these?
(No,Deltay,Betay,Length,Coefficient,Power,Minimum) <N> L
Note: For infinity, RML = 0.0
Enter the desired Monin-Obukhov length: (m) -140.

(9) The values for the atmospheric parameters are set as follows:
DELTAY:                          0.1046
BETAY:                           0.9000
Monin-Obukhov length:         -140.0000 m
Sigma X Coefficient:             0.0200
Sigma X Power:                   1.2200
Sigma X Minimum Distance:      130.0000 m
Do you wish to change any of these?
(No,Deltay,Betay,Length,Coefficient,Power,Minimum) <N>

(10) Enter the ambient temperature(K) and pressure(atm): 305.88,0.94

The ambient humidity can be entered as Relative or Absolute.
Enter either R or A <R or a>:
Enter the relative humidity (%): 12.5

(11) Ambient Air density is    1.081886     kg/m**3

(12) Is this an Isothermal spill? <y or N>

(13) Is heat transfer to be included in the calculations <y or N> Y
Enter the surface temperature [=] K : 310.
Do you want to use the built in correlation, the LLNL correlation, or
enter a particular value?
(Corr,LLNLcorr,Value)  <C>

(14) Is water transfer to be included in the source <y or N>
```

(15) Enter the three-letter designation of the diffusing gas. The properties of LNG as methane, LPG as propane, and NH_3 (ammonia) are included among others.

(16) A list of the properties for the specified gas (if available) is given. If any of the parameters are to be changed, the first letter of the parameter to be changed in the list is given to the prompt. Here, the level at which the flammability contours are calculated is changed from 0.5 m to 1.0 m.

(17) The gas property list is displayed again. The default response is no change.

(18) The lowest concentration of interest is the concentration at which the calculations are stopped.

(19) The BURRO9 case is for a release of "pure" (undiluted) LNG. For diluted releases, DEGADIS requires the mass fraction of the contaminant and the mixture temperature.

(20) If a steady-state release is to be simulated, type "Y" to the prompt. For a steady simulation, the steady-state mass evolution rate (kg/s) and primary source extent (m) are required.

(21) A note about the numerical parameter files is included. These files contain various constant values used in the programs to which the user has access without recompiling the programs. Access is granted as a convenience.

(22) DEGADISIN will generate a command procedure suitable for running the model under VMS.

(23) If so desired, DEGADISIN will initiate the command procedure under VMS. If not, the program returns to the operating system.

(15) Enter the code name of the diffusing species: LNG

(16)
```
The characteristics for the gas are set as follows:
Molecular weight:                                16.04
Storage temperature [K]:                          111.70
Density at storage temperature, PAMB  [kg/m**3]:   1.6845
Mean Heat capacity constant                     5.60000E-08
Mean Heat capacity power                          5.0000
Upper Flammability Limit [mole frac]              0.15000
Lower Flammability Limit [mole frac]            5.00000E-02
Height of Flammability Limit [m]                  0.50000
Do you wish to change any of these? (No,Mole,Temp,Den,Heat,Power,Upper,Lower,Z)
<N> Z
Enter the desired Height for the flammable limit calculations: 1.
```

(17)
```
The characteristics for the gas are set as follows:
Molecular weight:                                16.04
Storage temperature [K]:                          111.70
Density at storage temperature, PAMB  [kg/m**3]:   1.6845
Mean Heat capacity constant                     5.60000E-08
Mean Heat capacity power                          5.0000
Upper Flammability Limit [mole frac]              0.15000
Lower Flammability Limit [mole frac]            5.00000E-02
Height of Flammability Limit [m]                  1.0000
Do you wish to change any of these? (No,Mole,Temp,Den,Heat,Power,Upper,Lower,Z)
<N>
```

(18)
```
    The suggested LOWEST CONCENTRATION OF INTEREST (gas_lfl/2.)
     is   1.50191E-02 kg/m**3.  Enter the desired value: 0.015
```

Specification of source parameters.

(19) Is this a release of pure (P) or diluted (d) material specified above? <P or d>

(20) Is this a Steady state simulation? <y or N> Y

Enter the desired evolution rate [=] kg/sec : 130.
Enter the desired source radius [=] m : 22.06

(21) In addition to the information just obtained, DEGADIS requires a series of numerical parameter files which use the same name as [DIR]RUNNAME given above.

For convenience, example parameter files are included for each step. They are:
EXAMPLE.ER1 and
EXAMPLE.ER2
Note that each of these files can be edited during the course of the simulation if a parameter proves to be out of specification.

(22) Do you want a command file to be generated to execute the procedure? <Y or n>
The command file will be generated under the file name:
BURRO9S.com

(23) Do you wish to initiate this procedure? <y or N>
$

Notes on Transient Simulation of BURRO9

Beginning with the specification of the source rate and extent, the responses to all of the previous questions except the simulation name (RUN_NAME) are the same for the steady-state case and are not repeated.

(19) The BURRO9 case is for a release of "pure" (undiluted) LNG. For diluted releases, DEGADIS requires the mass fraction of the contaminant and the mixture temperature.

(20) The default response is for a transient release.

(21) An initial mass of gas can be specified over the source. This can be used to model aboveground releases such as the Thorney Island Trials.

(22) The transient source description consists of ordered triples of time, evolution rate, and source radius for pure sources. For diluted sources, values of evolution rate, source radius, contaminant mass fraction, and source temperature must be specified as functions of time.

(23) An input file can be used to enter the data triples to avoid typing errors or to use as output from another model such as a liquid spreading model. The file format is the same as the terminal entry format.

(24) The first item is the number of triples used in the description followed by the triples with the last two values showing no gas present.

(25) A note about the numerical parameter files is included. These files contain various constant values used in the programs to which the user has access without recompiling the programs. Access is granted as a convenience.

(26) DEGADISIN will generate a command procedure suitable for running the model under VMS.

(27) If so desired, DEGADISIN will initiate the procedure under VMS. If not, the program returns to the operating system.

```
(19) Specification of source parameters.

(20) Is this a release of pure (P) or diluted (d) material specified above? <P or d>

(21) Is this a Steady state simulation? <y or N>

Enter the initial mass of pure gas over the source. (kg)
(Positive or zero): 0.

(22)              Source Description

    The description of the primary source mass
    evolution rate E and radius R1 for a transient
    release is input by ordered triples as follows:

       first point        -- t=0, E(t=0), R1(t=0) (initial, nonzero values)
       second point       -- t=t1, E(t=t1), R1(t=t1)
              .
              .
              .

       last nonzero point -- t=TEND, E(t=TEND), R1(t=TEND)
       next to last point -- t=TEND+1., E=0., R1=0.
       last point         -- t=TEND+2., E=0., R1=0.

    Note: the final time (TEND) is the last time when E and R1 are non-zero.

(23) Do you have an input file for the Source Description? [y or N]

    Enter the number of triples (max= 30) starting with t=0. and ending
    with t=TEND+2. for the source description: 4

(24)    Enter TIME (sec), EVOLUTION RATE (kg/s), and POOL RADIUS (m)
0.,130.,22.06
80.,130.,22.06
81.,0.,0.
82.,0.,0.

(25) In addition to the information just obtained, DEGADIS
requires a series of numerical parameter files which use
the same name as [DIR]RUNNAME given above.

   For convenience, example parameter files are included for
each step.  They are:
         EXAMPLE.ER1,
         EXAMPLE.ER2, and
         EXAMPLE.ER3
 Note that each of these files can be edited during the course of the
simulation if a parameter proves to be out of specification.

(26) Do you want a command file to be generated to execute the procedure? <Y or n>
The command file will be generated under the file name:
         BURRO9.com

(27) Do you wish to initiate this procedure?  <y or N>
$
```

The INP files for BURRO9S and BURRO9 are shown in Figures B.8 and B.9. If necessary, the user may edit the INP file before beginning the simulation.

Example Simulation Output

BURRO9.LIS and BURRO9S.LIS contain the output listing for the transient and steady-state releases, respectively. A discussion of the steady-state and transient simulation listings follows. Because of the similarities between the steady-state and transient simulation listings, the first portion of the transient simulation is not included.

(3) Continuing with the input information, the contaminant gas properties are output.

(4) The specification of the mass evolution rate, source radius, contaminant mass fraction, and source temperature are output. For a steady-state release, there is no initial mass in the cloud, and the source parameters are held constant for an arbitrarily large period of time.

(5) Finally, certain numerical parameters and calculation flags are displayed. Some of these are set in DEGADISIN while others are set in the numerical parameter files.

(6) A summary of the calculated secondary source parameters is included. The secondary source gas radius and height are output as functions of time along with other secondary parameters including the source mass flux (Qstar), the vertical concentration distribution parameter at the downwind edge (SZ(x = L/2.)), the contaminant mole fraction (Mole frac C), the gas mixture density (Density), and the Richardson number based on the cloud spreading velocity (Rich No.).

(7) For a steady-state release, the source calculations are terminated after the calculated parameters are no longer changing as a function of time. A summary of the steady-state secondary source is included.

(8) The downwind portion of the calculations is included. The distance downwind of the source is given in the first column. Columns 2 through 6 contain the mole fraction, contaminant concentration, mixture density, ratio of $(\rho - \rho_a)/c_c$ (Gamma), and mixture temperature on the centerline of the gas cloud at ground level. Columns 7 through 9 contain the contour shape parameters b (Half Width), S_z, and S_y. Finally, columns 10 and 11 contain the width from the centerline to the indicated concentration levels at the indicated height. Note that the output is prematurely terminated. Output actually continues until the centerline, ground-level concentration drops below the lowest concentration of interest.

(3) Specified Gas Properties:

Molecular weight:	16.040	
Storage temperature:	111.70	K
Density at storage temperature and ambient pressure:	1.6845	kg/m**3
Mean heat capacity constant:	5.60000E-08	
Mean heat capacity power:	5.0000	
Upper mole fraction contour:	0.15000	
Lower mole fraction contour:	5.00000E-02	
Height for isopleths:	1.0000	m

(4) Source input data points

Initial mass in cloud: 0.00000E+00

Time	Contaminant Mass Rate	Source Radius	Contaminant Mass Fraction	Temperature	Enthalpy

Notes on Transient Simulation Output of BURRO9

(6) A summary of the calculated secondary source parameters is included. The secondary source gas radius and height are output as functions of time along with other secondary parameters including the source mass flux (Qstar), the vertical concentration distribution parameter at the downwind edge (SZ(x = L/2.)), the contaminant mole fraction (Mole frac C), the gas mixture density (Density), and the Richardson number based on the cloud spreading velocity (Rich No.). Note that only a portion of the output is shown. The source calculation ends when all the primary and secondary source gas has been taken up in the atmospheric flow.

(7) An indication of the constants used in the x-direction dispersion correction is included. The output will also indicate if the x-direction dispersion correction was not applied.

(8) The concentration field is shown for different times after the beginning of the spill. Unless otherwise specified, DEGADIS will choose default values for the time to output the concentration field. If other times are desired, DEGADIS3 can be executed again after the appropriate changes to RUN_NAME.ER3 have been made.

(9) The downwind portion of the calculations is included. The distance downwind of the source is given in the first column. Columns 2 through 6 contain the mole fraction, contaminant concentration, mixture density, ratio of $(\rho - \rho_a)/c_c$ (Gamma), and mixture temperature on the centerline of the gas cloud at ground level. Columns 7 through 9 contain the contour shape parameters b (Half Width), S_z, and S_y. Finally, columns 10 and 11 contain the width from the centerline to the indicated concentration levels at the indicated height. Note that the output is prematurely terminated.

Sorted values for each specified time.

(7) X-Direction correction was applied.
Coefficient: 2.00000E-02
Power: 1.2200
Minimum Distance: 130.00 m

(8) Time after beginning of spill 12.00000 sec

(9)

Distance (m)	Mole Fraction	Concentration (kg/m**3)	Density (kg/m**3)	Gamma	Temperature (K)	Half Width (m)	Sz (m)	Sy (m)	Width at z= 1.00 m to: 5.00 mole% (m)	15.0 mole (m)

In addition to the output of the concentration field at specified times (from DEGADIS3), DEGADIS allows for transient releases output of concentration time histories at specified positions using DEGADIS4. DEGADIS4 can be executed interactively or in batch mode. An example DEGADIS4 interactive run and output follow.

Notes on Using DEGADIS4

(1) DEGADIS4 can be run interactively as demonstrated here or in batch mode by supplying the same responses demonstrated here. DEGADIS4 sends the output to RUN_NAME.SR4.

(2) The RUN_NAME of the transient simulation is used here.

(3) The number of downwind positions where output is desired is entered here. For each downwind distance, questions 4 and 5 are required.

(4) The x-coordinate is the downwind distance from the source where output is desired.

(5) At each downwind distance, DEGADIS4 asks for the y- and z-coordinates desired. DEGADIS4 automatically supplies information about the centerline concentration (y = 0 and z = 0). Note that negative numbers signal that no more positions are desired for this particular downwind distance.

```
Enter the file name used for this run: BURRO9
Enter the number of downwind distances desired:
 max of           10 downwind distances; 4 positions at each distance
1

enter the x coordinate:

Notes on DEGADIS4 Output

(1) DEGADIS4 indicates the constants used in the x-direction dispersion correction. The user has the option of not making the x-direction dispersion correction if desired by making the appropriate changes to RUN_NAME.ER3.

(2) At each downwind distance specified, the concentration profile parameters are output as a function of time. Note that part of the output has been removed.

(3) DEGADIS4 outputs the concentration time history at the off-centerline positions specified.

(1) X-Direction correction was applied.
Coefficient: 2.00000E-02
Power: 1.2200
Minimum Distance: 130.00 m

(2) Centerline values for the position -->
x: 100.00 m

```
      Program jetplu_in
c
c
c     JETPLU_IN is designed to perform two tasks including:
c
c     a) Read the input file for the JETPLU/DEGADIS model input.  From
c     this information, JETPLU_IN prepares the necessary file to run the
c     JETPLU/DEGADIS model.
c
c     b) Generate a command file to execute the JETPLU/DEGADIS model from
C     the input information.  This portion is highly dependent on the
c     VAX/VMS environment because of the manipulation of character strings
c     and the instructions necessary to invoke the VAX/VMS commands.
c
c.....................................................................
c
c     This program can be invoked interactively or in a command file
c     submitted to batch.  For either case, the syntax is:
c
c     $ RUN SYS$DEGADIS:JETPLU_IN
c     RUN_NAME
c
c     where RUN_NAME is the file name given to the particular simulation.
c     The input file RUN_NAME.IN is to be created before this program
c     is invoked using free formats.  The order of input is as follows:
c
c     <TITLE1>
C     <TITLE2>
C     <TITLE3>
C     <TITLE4>
C
C     <UO>  <ZO>
C     <ZR>
C     <INDVEL>  <ISTAB>  <RML>
C     <TAMB>  <PAMB>  <RELHUM>
C     <TSURF>
C
C     <GASNAM>
C     <GASMW>
C     <AVTIME>
C     <TEMJET>
C     <GASUL>  <GASLL>  <ZLL>
C     <INDHT>  <CPK>  <CPP>
C     <NDEN>
C
C     <ERATE>
C     <ELEJET>  <DIAJET>
C     <TEND>
c     <DISTMX>
C
C     Note that for readability, blank lines were inserted between the

1 -- sys$degadis:jetplu_in.for              6-SEP-1989 19:57:57
```

```
c       input sections specifying a simulation title, atmospheric conditions,
c       gas properties, and the particular release conditions.  Symbol
c       definitions are as follows:
c
c       <TITLE1>, <TITLE2>, <TITLE3>, and <TITLE4> are four lines of up
c               to 80 characters each of a title for this simulation.
c
c       <U0> (m/s) is the ambient wind velocity at <Z0> (m).
c
c       <ZR> is the surface roughness (m).
c
c       <INDVEL> is an indicator which determines the method of calculation
c               for the ambient velocity profile in the jet/plume model as
c               follows:
c
c               For <INDVEL>=1, the Pasquill-Gifford stability category
c                  (in <ISTAB> using 1 for A, 2 for B, etc.) is used
c                  along with <ZR> to determine the Monin-Obukhov length
c                  <RML>; the log velocity profile is then determined
c                  using <RML>.
c
c               For <INDVEL>=2, the Monin-Obukhov length <RML> is supplied
c                  by the user; the log velocity profile is then determined
c                  using <RML>.  Note that <ISTAB> must still be specified.
c
c       <TAMB>, <PAMB>, and <RELHUM> are the ambient temperature (K), the
c               ambient pressure (atm or N/m**2), and the relative humidity (%),
c               respectively.
c
c       <TSURF> is the surface temperature (K); if <TSURF> < 250 K, <TSURF> is
c               set to <TAMB>.
c
c       <GASNAM> is a three-letter designation for the contaminant's name.
c               Any character string of three letters or less is valid; this
c               is for user run identification and does not access property
c               data.
c
c       <GASMW> is the contaminant's molecular weight (kg/kmole).
c
c       <AVTIME> is the averaging time (s).  This parameter is
c               used to estimate the value of <DELTAY>.
c
c       <TEMJET> is the temperature of the jet (K).
c
c       <GASUL> and <GASLL> are the concentrations to be used for estimating
c               contours for an upper and lower concentration level in
c               DEGADIS.  The calculations are made for the elevation
c               <ZLL>.  Note that the JETPLU/DEGADIS computations will be carried
c               out to <GASLL>/2.
c
c       <INDHT> is used to include heat transfer in the DEGADIS computations.
```

```
c               Heat transfer is not included for <INDHT>=0.  For <INDHT>=1,
c               heat transfer is included, and the heat transfer coefficient
c               is calculated by DEGADIS.  <CPP> and <CPK> are used to
c               calculate the heat capacity as a function of
c               temperature according to the correlation included in
c               DEGADIS.  If a constant heat capacity is
c               desired, set <CPP> to 0. and <CPK> to the desired heat
c               capacity (J/kg K).
c
c       <NDEN>  is used to specify the contaminant density profile.
c               There are three cases for <NDEN>:
c
c               <NDEN> = -1; The simulation treats the contaminant as if
c                       it were an ideal gas with a molal heat capacity
c                       equal to that of air.  Water condensation effects
c                       are ignored.  (equivalent to ISOFL=1 in DEGADIS)
c
c               <NDEN> = 0;  The simulation treats the contaminant as if
c                       it were an ideal gas with the heat capacity indicated
c                       by <CPK> and <CPP>.  Water condensation effects
c                       are taken into account as appropriate.
c                       (equivalent to ISOFL=0 in DEGADIS)
c
c               <NDEN> > 0; <NDEN> specifies the number of triples which follow
c                       in the next <NDEN> lines.  The triples are used to
c                       specify the contaminant concentration as a function of
c                       density based on adiabatic mixing with ambient air.
c                       The ordered triples represent (in order):
c                         (1) the contaminant mole fraction
c                         (2). the contaminant concentration (kg contam/m3 mix)
c                         (3) the mixture density (kg mixture/m3 mixture)
c                       The ordered triples must go from pure air to pure
c                       contaminant.  (equivalent to ISOFL=1 in DEGADIS)
c
c       <ERATE> is the mass evolution (release) rate (kg/s).
c
c       <ELEJET> is the inital jet elevation (m); the minimum jet elevation
c               is twice the surface roughness.  <DIAJET> is the initial
c               jet diameter (m).
c
c       <TEND> is the duration of the primary release (s).  For steady-state
c               releases, set <TEND> to 0.; to run the jet/plume model only, set
c               <TEND> to a negative number.
c
c       <DISTMX> is the maximum distance between output points in the JETPLU
c               output (m).

      PROGRAM JETPLU_MAIN
C
c-----------------------------------------------------------------------
c
c       This program calculates the trajectory and dilution of a steady
c       gas jet released at right angles to the wind.  The zone before Gaussian
c       profiles can be assumed for the velocity and concentration profiles
c       is termed the zone of flow establishment; calculations for this zone
c       are done in the routine SETJET.  The zone after Gaussian profiles can
c       be assumed to apply is termed the zone of established flow.  The
c       ordinary differential equations describing this zone are included in
c       MODEL; these are integrated with the routine RKGST.  Interactions
c       between the jet/plume and the ground are accounted for using the method
c       of images.

      PROGRAM DEGADIS4
C
C*************************************************************************
C*************************************************************************
C*************************************************************************
C
C       Program description:
C
C       DEGADIS4 sorts the downwind dispersion calculation made for each of
C       the several observers in DEGADIS2.  The output concentrations at
C       several given times may then be corrected for along-wind dispersion
C       as desired.  DEGADIS4 also outputs the concentration as a function
C       of time at a given position.
C
C
C       Program usage:
C
C       Consult Volume III of the Final Report to U. S. Coast Guard

C
C*** This subroutine sets the default time sort windows.
C
C*** The first sort time is set for potential low wind speed cases,
C***   while the last sort time is set for potential high wind speed
C***   cases.  The first sort time is taken to be when the first
C***   observer passes through x=RMAX.  The last sort time is taken
C***   to be when the last observer passes through x=6*RMAX.
C***   The default value for the number of sort times is set to 10.
C***   Obviously, these values generate some sort times which will be
C***   useless; hopefully, these values will show the user where to
C***   look on the next go around.
C*** The number of times has been doubled to 20 and the time interval
C***   has been doubled in order to give more information for lower
C***   concentrations (for the toxic gas problem). tos,5mar86

C      ...................................................
C
C      SUBROUTINE RKGST
C
C.....................................................
c
c      This routine was originally supplied by Digital Equipment
c      Corporation as part of the Scientific Subroutine Package
c      available for RT-11 as part of the Fortran Enhancement
c      Package.  It was upgraded for use as the integration
c      routine in this package.
c
C.....................................................
c
C      PURPOSE
C              TO SOLVE A SYSTEM OF FIRST ORDER ORDINARY DIFFERENTIAL
C              EQUATIONS WITH GIVEN INITIAL VALUES.
C
C      USAGE
C              CALL RKGST (PRMT,Y,DERY,NDIM,IHLF,FCT,OUTP,AUX)
C              PARAMETERS FCT AND OUTP REQUIRE AN EXTERNAL STATEMENT.
C
C      DESCRIPTION OF PARAMETERS
C
C      PRMT    AN INPUT AND OUTPUT VECTOR WITH DIMENSION GREATER
C              OR EQUAL TO 5, WHICH SPECIFIES THE PARAMETERS OF
C              THE INTERVAL AND OF ACCURACY AND WHICH SERVES FOR
C              COMMUNICATION BETWEEN SUBROUTINES OUTP AND FCT
C              (FURNISHED BY THE USER) AND SUBROUTINE RKGST.
C              EXCEPT PRMT(5) THE COMPONENTS ARE NOT DESTROYED
C              BY SUBROUTINE RKGST AND THEY ARE:
C      PRMT(1) LOWER BOUND OF THE INTERVAL (INPUT),
C      PRMT(2) UPPER BOUND OF THE INTERVAL (INPUT),
C      PRMT(3) INITIAL INCREMENT OF THE INDEPENDENT VARIABLE
C              (INPUT),
C      PRMT(4) UPPER ERROR BOUND (INPUT). IF RELATIVE ERROR IS
C              GREATER THAN PRMT(4), INCREMENT GETS HALVED.
C              IF RELATIVE ERROR LESS THAN PRMT(4)*EXPAND,
C              INCREMENT GETS DOUBLED.
C              THE USER MAY CHANGE PRMT(4) BY MEANS OF HIS
C              OUTPUT SUBROUTINE.
C      PRMT(5) MAXIMUM STEP SIZE ORDER OF MAGNITUDE (INPUT).
C              SUBROUTINE RKGST INITIALIZES
C              PRMT(5)=0. IF THE USER WANTS TO TERMINATE
C              SUBROUTINE RKGST AT ANY OUTPUT POINT, HE HAS TO
C              CHANGE PRMT(5) TO NON-ZERO BY MEANS OF SUBROUTINE
C              OUTP. FURTHER COMPONENTS OF VECTOR PRMT ARE
C              FEASIBLE IF ITS DIMENSION IS DEFINED GREATER
C              THAN 5. HOWEVER SUBROUTINE RKGST DOES NOT REQUIRE
C              AND CHANGE THEM. NEVERTHELESS THEY MAY BE USEFUL
C              FOR HANDING RESULT VALUES TO THE MAIN PROGRAM
```

```
C               (CALLING RKGST) WHICH ARE OBTAINED BY SPECIAL
C               MANIPULATIONS WITH OUTPUT DATA IN SUBROUTINE OUTP.
C       Y       INPUT VECTOR OF INITIAL VALUES.  (DESTROYED)
C               LATER, Y IS THE RESULTING VECTOR OF DEPENDENT
C               VARIABLES COMPUTED AT INTERMEDIATE POINTS X.
C       DERY    INPUT VECTOR OF ERROR WEIGHTS.  (DESTROYED)
C               ERROR WEIGHTS ARE CENTERED AT ONE. IF ONE PARA-
C               METER NEEDS A TIGHTER ERROR CRITERIA,THE WEIGHT IS
C               GREATER THAN ONE. IF A PARAMETER NEED NOT BE DETER-
C               MINED SO PRECISELY,THE WEIGHT SHOULD BE LESS
C               THAN ONE.IN OTHER WORDS,
C                       ERROR CRITERIA(I) = PRMT(4) / WEIGHT(I)
C               WHERE I IS THE SUBSCRIPT OF A DEPENDENT VARIABLE.
C               LATER, DERY IS THE VECTOR OF DERIVATIVES, WHICH
C               BELONG TO FUNCTION VALUES Y AT A POINT X.
C       NDIM    AN INPUT VALUE, WHICH SPECIFIES THE NUMBER OF
C               EQUATIONS IN THE SYSTEM.
C       IHLF    AN OUTPUT VALUE, WHICH SPECIFIES THE NUMBER OF
C               BISECTIONS OF THE INITIAL INCREMENT. IF IHLF BE-
C               COMES GREATER THAN 10, SUBROUTINE RKGST RETURNS THE
C               ERROR MESSAGE IHLF=11 INTO MAIN PROGRAM. ERROR
C               MESSAGE IHLF=12 OR IHLF=13 APPEARS IN CASE
C               PRMT(3)=0 OR IN CASE SIGN(PRMT(3)).NE.SIGN(PRMT(2)-
C               PRMT(1)) RESPECTIVELY.
C       FCT     THE NAME OF AN EXTERNAL SUBROUTINE USED. THIS
C               SUBROUTINE COMPUTES THE RIGHT HAND SIDES DERY OF
C               THE SYSTEM TO GIVEN VALUES X AND Y. ITS PARAMETER
C               LIST MUST BE X,Y,DERY,PRMT. SUBROUTINE FCT SHOULD
C               NOT DESTROY X AND Y.
C       OUTP    THE NAME OF AN EXTERNAL OUTPUT SUBROUTINE USED.
C               ITS PARAMETER LIST MUST BE X,Y,DERY,IHLF,NDIM,PRMT.
C               NONE OF THESE PARAMETERS (EXCEPT, IF NECESSARY,
C               PRMT(4),PRMT(5),...) SHOULD BE CHANGED BY
C               SUBROUTINE OUTP. IF PRMT(5) IS CHANGED TO NON-ZERO,
C               SUBROUTINE RKGST IS TERMINATED.
C       AUX     AN AUXILIARY STORAGE ARRAY WITH 8 ROWS AND NDIM
C               COLUMNS.
C
C       REMARKS
C
C       THE PROCEDURE TERMINATES AND RETURNS TO CALLING PROGRAM, IF
C       (1) MORE THAN 10 BISECTIONS OF THE INITIAL INCREMENT ARE
C               NECESSARY TO GET SATISFACTORY ACCURACY (ERROR MESSAGE
C               IHLF=11),
C       (2) INITIAL INCREMENT IS EQUAL TO 0 OR HAS WRONG SIGN
C               (ERROR MESSAGES IHLF=12 OR IHLF=13),
C       (3) THE WHOLE INTEGRATION INTERVAL IS WORKED THROUGH,
C       (4) SUBROUTINE OUTP HAS CHANGED PRMT(5) TO NON-ZERO.
C
C       SUBROUTINES AND FUNCTION SUBPROGRAMS REQUIRED
C       THE EXTERNAL SUBROUTINES FCT(X,Y,DERY,PRMT) AND
```

```
C       OUTP(X,Y,DERY,IHLF,NDIM,PRMT) MUST BE FURNISHED BY THE USER.
C
C       METHOD
C       EVALUATION IS DONE BY MEANS OF FOURTH ORDER RUNGE-KUTTA
C       FORMULAE IN THE MODIFICATION DUE TO GILL. ACCURACY IS
C       TESTED COMPARING THE RESULTS OF THE PROCEDURE WITH SINGLE
C       AND DOUBLE INCREMENT.
C       SUBROUTINE RKGST AUTOMATICALLY ADJUSTS THE INCREMENT DURING
C       THE WHOLE COMPUTATION BY HALVING OR DOUBLING. IF MORE THAN
C       10 BISECTIONS OF THE INCREMENT ARE NECESSARY TO GET
C       SATISFACTORY ACCURACY, THE SUBROUTINE RETURNS WITH
C       ERROR MESSAGE IHLF=11 INTO MAIN PROGRAM.
C       TO GET FULL FLEXIBILITY IN OUTPUT, AN OUTPUT SUBROUTINE
C       MUST BE FURNISHED BY THE USER.

C
C       RELATIVE ERROR
C       -------- -----
C
C       AS PER RICHARDSON QUOTED IN RALSTON/WILF (P117),
C
C       ABS ERROR = WEIGHT/15*ABS(Y2 - Y1)
C
C       THEN, RELATIVE ERROR
C
C       REL ERROR = WEIGHT*2/15*ABS(Y2 - Y1)/SUM
c
c       where SUM = ABS(Y2 + Y1)
C
C       The solution tries to use SUM=abs(y2+y1) first. If this is zero,
C       then SUM=.25*ABS(Y1) is used since y1 and y2 must be oposite in
C       sign with equal magnitude. If this
C       quantity is zero as well, the values y2 and y1 both must be zero;
C       therefore, the difference is also zero which satisfies the
C       error criteria.

      PROGRAM DEGBRIDGE
C
c-----------------------------------------------------------------------
c
C       Program description:
C
C       DEGBRIDGE is designed to read the input file for the OOMS/DEGADIS
C       model input.  From this information and the output from the OOMS model,
C       DEGBRIDGE prepares the necessary input file to run DEGADIS
c       (RUN_NAME.INP).
C
c-----------------------------------------------------------------------
c
c       The structure of the RUN_NAME.IN file is outlined in OOMS_IN.
c
c       The output file from the OOMS model contains three (3) variables
c       as follows (in RUN_NAME.IND):
c
c       <DIST>  <CC>  <HWIDTH>
c
c       where:
c
c         <DIST>   is the distance to the centerline touchdown (m)
c         <CC>     is the centerline concentration at <DIST>
c         <HWIDTH> is jet/plume half width at <DIST>
c
c       To establish the initial conditions for DEGADIS, the source
c       concentration is assumed to be <CC>, and the source radius is assumed
c       to be <HWIDTH>.
C
c-----------------------------------------------------------------------
c
C       Program usage:
C
C       Consult Volume III of the Final Report to U. S. Coast Guard
C       contract DT-CG-23-80-C-20029 entitled "Development of an
C       Atmospheric Dispersion Model for Heavier-than-Air Gas Mixtures".

APPENDIX F

PARTIAL LISTING OF PROGRAM VARIABLES

Variable	Data Type	Symbol	Units	Comments
AGAIN	LOGICAL			Local communications in SSSUP
ALEPH	REAL			Collection of constants to calculate observer position and velocity
ALPHA	REAL	α	n/a	Power law velocity profile power
ALPHA1	REAL	$(1.0 + \alpha)$	n/a	
BETAY	REAL	β_y	n/a	Lateral similarity power
CCLOW	REAL		kg/m^3	Lowest mixture concentration of interest
CHECK1	LOGICAL			Unused logical flag
CHECK2	LOGICAL			When true, release type without a liquid source
CHECK3	LOGICAL			Local communications flag used in DEGADIS1
CHECK4	LOGICAL			When true, steady-state simulation
CHECK5	LOGICAL			When true, user sets time-sort parameters
DELTAY	REAL	δ_y	$m^{1-\beta}$	Lateral similarity coefficient
DEN(1,I)	REAL	y_c	mole fraction	Contaminant mole fraction
DEN(2,I)	REAL	c_c	kg/m^3	Contaminant concentration for the given mole fraction

Variable	Data Type	Symbol	Units	Comments
DEN(3,I)	REAL	ρ	kg/m^3	Mixture density for the given mole fraction
DEN(4,I)	REAL	h	J/kg	Mixture enthalpy for the given mole fraction
DEN(5,I)	REAL	T	K	Mixture temperature for the given mole fraction
EMAX	REAL		kg/s	Maximum of secondary source mass evolution rate
ESS	REAL	E	kg/s	Steady-state release rate
ET(I)	REAL	E(t)	kg/s	Source mass evolution rate as a function of time PTIME(I)
G	REAL	g	m/s^2	Acceleration due to gravity
GAMMAF	REAL	$\Gamma(1/(1+\alpha))$	n/a	
GAS_CPK	REAL	q_1	J/kmol K^{p_1-1}	Constant for contaminant heat capacity
GAS_CPP	REAL	p_1	n/a	Power for contaminant heat capacity
GAS_LFL	REAL		mole fraction	Lower contaminant concentration level for estimating contours
GAS_MW	REAL	MW_C	kg/kmol	Contaminant molecular weight
GAS_NAME	CHARACTER*3			Name of contaminant
GAS_RHOE	REAL	ρ_0	kg/m^3	Saturated vapor density of contaminant at T_0
GAS_TEMP	REAL	T_0	K	Contaminant storage temperature
GAS_UFL	REAL		mole fraction	Upper contaminant concentration level for estimating contours

Variable	Data Type	Symbol	Units	Comments
GAS_ZSP	REAL		m	Height for estimating contours
GMASS0	REAL		kg	Initial mass of gas over the primary source
HTCO	REAL	h_0	J/m^2sK	Constant coefficient when IHTFL=-1
		V_H	m/s	LLNL heat transfer velocity when IHTFL=2
HUMID	REAL		kg water/ kg dry air	Ambient absolute humidity
IHTFL	INTEGER			Heat transfer flag: IHTFL=-1 constant coefficient IHTFL=0 no heat transfer IHTFL=1 DEGADIS correlation IHTFL=2 LLNL correlation
ISOFL	INTEGER			Isothermal release when ISOFL=1
ISTAB	INTEGER			Pasquill atmospheric stability indicator (ISTAB=1 for A, (ISTAB=2 for B, etc.)
IWTFL	INTEGER			Water transfer flag IWTFL=-1 constant coefficient IWTFL=0 no water transfer IWTFL=1 DEGADIS correlation
K	REAL	k	n/a	von Karman's constant, 0.35
LUNLOG	INTEGER			Fortran logical unit number which acts as a simulation log
MAXNOB	INTEGER			Maximum number of observers
ML	REAL	λ	m	Monin-Obukhov length
NOBS	INTEGER			Number of observers for the pseudosteady-state simulation

Variable	Data Type	Symbol	Units	Comments
NREC(I,1)	INTEGER			Number of records generated in PSSOUT for observer I
NREC(I,2)	INTEGER			Number of records generated in SSGOUT for observer I
PAMB	REAL	p	atm	Ambient pressure
POUND	CHARACTER*4			Character string to signal end of data ('// ')
POUNDN	REAL			Numerical value to signal end of data (-1.E-20)
QSTR(1,I)	REAL	t	s	Independent variable time for ordered pairs QSTR
QSTR(2,I)	REAL	Q*	kg/m^2s	Atmospheric takeup rate as a function of time
RADG(1,I)	REAL	t	s	Independent variable time for ordered pairs RADG
RADG(2,I)	REAL	R	m	Secondary source radius as a function of time
RELHUMID	REAL		%	Ambient relative humidity
RHOA	REAL	ρ_a	kg/m^3	Ambient air density
RM	REAL	R_m	m	Radius at EMAX (when secondary source mass evolution rate is a maximum)
RMAX	REAL	R_{max}	m	Maximum secondary source radius
RT2	REAL	$\sqrt{2}$.	n/a	Constant
R1SS	REAL	R_p	m	Steady-state primary source radius

Variable	Data Type	Symbol	Units	Comments
R1T(I)	REAL	R_p	m	Primary source radius as a function of time PTIME(I)
SIGX_COEFF	REAL			Along-wind similarity coefficient
SIG_MIN_DIST	REAL		m	Minimum distance to apply x-direction dispersion correction
SIGX_POW	REAL		n/a	Along-wind similarity power
SLEN	REAL	L	m	Steady-state source length
SQPIO2	REAL	$\sqrt{\pi/2}$.	n/a	Constant
SQRTPI	REAL	$\sqrt{\pi}$	n/a	Constant
SRCDEN(1,I)	REAL	t	s	Independent variable time for ordered pairs SRCDEN
SRCDEN(2,I)	REAL	ρ	kg/m^3	Secondary source density as a function of time
SRCENTH(1,I)	REAL	t	s	Independent variable time for ordered pairs SRCENTH
SRCENTH(2,I)	REAL	h	J/kg	Secondary source enthalpy as a function of time
SRCWA(1,I)	REAL	t	s	Independent variable time for ordered pairs SRCWA
SRCWA(2,I)	REAL	w_a	mass fraction	Secondary source air mass fraction as a function of time
SRCWC(1,I)	REAL	t	s	Independent variable time for ordered pairs SRCWC

Variable	Data Type	Symbol	Units	Comments
SRCWC(2,I)	REAL	w_c	mass fraction	Secondary source contaminant mass fraction as a function of time
SWID	REAL		m	Steady-state source half-width
SZM	REAL	S_{z0m}	m	Value of S_{z0} at EMAX (when secondary source mass evolution rate is a maximum)
TAMB	REAL	T	K	Ambient temperature
TEND	REAL		s	Termination time of secondary source
TINP	CHARACTER*24			Time DEGADISIN was executed
TITLE(1:4)	CHARACTER*80			Text title block 4 lines of 80 spaces
TO(I)	REAL		s	Time of release for observer I
TSURF	REAL	T_s	K	Surface temperature
USTAR	REAL	u_*	m/s	Friction velocity
UO	REAL	u_0	m/s	Ambient velocity at height z_0
WTCO	REAL	F	kg/m^2s	Mass transfer coefficient when IWTFL=-1
XV(I)	REAL	x_v	m	Virtual source position for estimation of S_y in SSG
ZO	REAL	z_0	m	Height for velocity u_0
ZR	REAL	z_R	m	Roughness length

APPENDIX G
DEGADIS DIAGNOSTIC MESSAGES

To assist the user in determining the source of any problems, a diagnostic procedure has been included in DEGADIS. The subroutine TRAP is meant to cause an orderly termination of the program for many detected errors. It performs two basic functions: TRAP displays an error code and a single line diagnostic message giving the reason for premature termination, and TRAP forces an output of the COMMON area data sets to the file TRAP.DBG.

The first three lines sent to the execution log (default=TERMINAL) include the TRAP introductory lines and the error code number:

```
The best laid plans of mice and men . . .
You have entered a TRAP--THE LAND OF NO RETURN
CODE:  NN
```

where NN represents the code of the error message which follows in the log. The error message begins with the name of the calling routine.

The following is a list of the error codes, error messages, and suggested actions for each problem.

Code: 1

DEGADIS1? Source integration has returned IHLF=NN

Action: This error occurs during integration of the equations which describe the gas source. IHLF is an error code returned by the integration package RKGST.

When IHLF=11, more than 10 bisections of the initial increment of the independent variable were necessary to make an integration step within the specified error. Reduce the initial step size of the independent variable (STPIN in the ER1 file). If this does not work, it will be necessary to either increase the error criteria for all of the dependent variables being integrated (ERBND in the ER1 file) or increase the error criteria for the variable violating the criteria by decreasing the error weight for that variable (one of the following: WTRG, WTTM, WTYA, WTYC, WTEB, WTMB, or WTUH in the ER1 file).

When IHLF=12, the initial increment of the independent variable (STPIN) is 0. Correct the ER1 file and execute the program again.

When IHLF=13, the initial increment of the independent variable (STPIN) is not the same sign as the difference between the upper bound of the interval and the lower bound of the interval. STPIN must be positive. Correct the ER1 file and execute the program again.

Code: 2
Reserved

Code: 3
SZF? Local integration failed; IHLF=NN

Action: This error occurs during estimation of SZ over the source when no gas is present. IHLF is an error code returned by the integration package RKGST.

When IHLF=11, more than 10 bisections of the initial increment of the independent variable were necessary to make an integration step within the specified error. Reduce the initial step size of the independent variable (SZSTP0 in the ER1 file). If this does not work, increase the error criteria for all of the dependent variables being integrated (SZERR in the ER1 file).

When IHLF=12, the initial increment of the independent variable (SZSTP0) is 0. Correct the ER1 file and execute the program again.

When IHLF=13, the initial increment of the independent variable (SZSTP0) is not the same sign as the difference between the upper bound of the interval and the lower bound of the interval. SZSTP0 must be positive. Correct the ER1 file and execute the program again.

Code: 4
SURFACE? Negative QRTE for positive DELTA_T.

Action: This is a diagnostic message indicating an error in estimation of the heat capacity. Check the input to the model and execute the program again.

Code: 5
CRFG? More points for GEN3 were needed.

Action: The COMMON area /GEN3/ stores representative values of the calculated source parameters. If this message occurs, relax the CRFG error criteria (CRFGER) in the ER1 file. If this is a common problem, the length of the /GEN3/ vectors can be increased by changing the value of MAXL in DEGADIS1.DEC and reinstalling DEGADIS.

Code: 6
TUPF? Observer calculations--TUPF failed

Action: The trial-and-error search associated with finding the upwind edge of the gas source for an observer failed. Often this problem can be avoided by adding one or two additional observers to the present number of observers (which changes the conditions for the trial and error). Another possibility is to increase the error criteria for this function (ERTUPF) in the ER2 file.

Code: 7
TDNF? Observer calculations--TDNF failed

Action: The trial-and-error search associated with finding the downwind edge of the gas source for an observer failed. Often this problem can be solved by adding one or two additional observers to the present number of observers (which changes the conditions for the trial and error). Another possibility is to increase the error criteria for this function (ERTDNF) in the ER2 file.

Code: 8
SSSUP? Observer Integration failed, IHLF=NN

Action: This error occurs during integration of the five differential equations which average the source for each observer. IHLF is an error code returned by the integration package RKGST.

When IHLF=11, more than 10 bisections of the initial increment of the independent variable were necessary to make an integration step within the specified error. Reduce the initial step size of the independent variable (STPO in the ER2 file). If this does not work, it will be necessary to either increase the error criteria for all of the dependent variables being integrated (ERRO in the ER2 file) or increase the error criteria for the variables violating the criteria by decreasing the error weight for that variable (one of the following: WTAIO, WTQOO, or WTSZO in the ER2 file).

When IHLF=12, the initial increment of the independent variable (STPO) is 0. Correct the ER2 file and execute the program again.

When IHLF=13, the initial increment of the independent variable (STPO) is not the same sign as the difference between the upper bound of the interval and the lower bound of the interval. STPO must be positive. Correct the ER2 file and execute the program again.

Code: 9

SSSUP/SDEGADIS2? Pseudosteady Integration failed, IHLF=NN

Action: This error occurs during integration of the four differential equations describing the portion of the downwind calculation when b > 0. The routine calling TRAP is SSSUP if a transient simulation is being executed; if a steady-state simulation is being executed, the calling routine is SDEGADIS2. IHLF is an error code returned by the integration package RKGST.

When IHLF=11, more than 10 bisections of the initial increment of the independent variable were necessary to make an integration step within the specified error. Reduce the initial step size of the independent variable (STPP in the ER2 file). If this does not work, it will be necessary to either increase the error criteria for all of the dependent variables being integrated (ERRP in the ER2 file) or increase the error criteria for the variable violating the criteria by decreasing the error weight for that variable (one of the following: WTSZP, WTSYP, WTBEP, or WTDH in the ER2 file).

When IHLF=12, the initial increment of the independent variable (STPP) is 0. Correct the ER2 file and execute the program again.

When IHLF=13, the initial increment of the independent variable (STPP) is not the same sign as the difference between the upper bound of the interval and the lower bound of the interval. STPP must be positive. Correct the ER2 file and execute the program again.

Code: 10

SSSUP/SDEGADIS2? Gaussian Integration fail, IHLF=nn

Action: This error occurs during integration of the differential equations describing the portion of the downwind calculation when b=0. The routine calling TRAP is SSSUP if a transient simulation is being executed; if a steady-state simulation is being executed, the calling routine is SDEGADIS2. IHLF is an error code returned by the integration package RKGST.

When IHLF=11, more than 10 bisections of the initial increment of the independent variable were necessary to make an integration step within the specified error. Reduce the initial step size of the independent variable. (STPG in the ER2 file). If this does not work, it will be necessary to either increase the error criteria for all of the dependent variables being integrated (ERRG in the ER2 file) or increase the error criteria for the variable violating the criteria by decreasing the error weight for that variable (either WTRUH or WTDHG in the ER2 file).

When IHLF=12, the initial increment of the independent variable (STPG) is 0. Correct the ER2 file and execute the program again.

When IHLF=13, the initial increment of the dependent variable (STPG) is not the same sign as the difference between the upper bound of the interval and the lower bound of the interval. STPG must be positive. Correct the ER2 file, and execute the program again.

Code: 11
SSSUP/SDEGADIS2 Total No. of Records exceeds 120,000

Action: This is an arbitrary stopping point for the process in order to keep a runaway simulation from filling up disk space. Relax the output specification (ODLP, ODLLP, ODLG, or, DLLG) in the ER2 file in order to generate less output if the input parameters are valid.

Code: 12
Reserved

Code: 13
Reserved

Code: 14
Reserved

Code: 15
Reserved

Code: 16
PSSOUT/PSSOUTSS? PSS started with B < 0.

Action: This condition is checked at the beginning of the downwind calculation in order to confirm proper handling of the movement to the Gaussian phase of the downwind calculation. Check the initial conditions and execute the program again.

Code: 17
TPROP/ADDHEAT? Enthalpy out of bounds

Action: Diagnostic message indicating that an enthalpy lower than the adiabatic mixing enthalpy was passed to ADDHEAT. Check the input conditions and execute the program again.

Code: 18
ALPH? ALPHA integration failed, IHLF=NN

Action: The integration which determines the integral least squares fit for ALPHA has failed. Note that small values of the Monin-Obukhov length (ML < O(1m)) in combination with stable atmospheric conditions may cause this failure. IHLF is an error code returned by the integration package RKGST.

When IHLF=11, more than 10 bisections of the initial increment of the independent variable were necessary to make an integration step within the specified error. Reduce the absolute value of the initial step size of the independent variable (STPINZ in the ER1 file). If this does not work, it will be necessary to increase the error criteria (ERBNDZ in the ER1 file).

When IHLF=12, the initial increment of the independent variable (STPINZ) is 0. Correct the ER1 file and execute the program again.

When IHLF=13, the initial increment of the independent variable (STPINZ) is not the same sign as the difference between the upper bound of the interval and the lower bound of the interval. STPINZ must be negative. Correct the ER1 file and execute the program again. This error will also occur if the surface roughness ZR is greater than the reference height Z0.

Code: 19
ALPH? RTMI has failed to locate ALPHA IERR:NN

Action: The search procedure which determines ALPHA has failed. This error may be the result of an unusual velocity specification such as small values of the Monin-Obukhov length (ML < O(1.m)) or small reference heights (Z0 < O(10. * ML)). IERR is an error code returned by the routine RTMI.

When IERR=1, the search for ALPHA failed after a specified number of iterations. Increase the error bound used by RTMI (EPS in the ER1 file).

When IERR=2, the basic assumption that the function which governs the search for ALPHA changes sign over the specified interval is false. Increase the search interval by decreasing the lower bound of ALPHA (XLI in the ER1 file) and increasing the upper bound (XRI in the ER1 file).

Code: 20
ESTRT? Premature EOF in RUN_NAME.ER1 or RUN_NAME.ER2

Action: The portion of the program which reads ER1 and ER2 files encountered an end-of-file mark before all of the information had been read. Confirm these files and execute the program again. If necessary, copy and edit the appropriate EXAMPLE file and execute the program again.

Code: 21
ESTRT1/ESTRT2/ESTRT2SS/ESTRT3? DECODE failed.

Action: The portion of the program which reads the ER1, ER2, or the ER3 file failed to understand a numerical entry. The numbers must appear in columns 11-20 of the line with no alphabetic characters in the field. (Note that exponential notation is not allowed.) This restriction does not apply to comment lines which have an exclamation point (!) in the first column.

Code: 22
ESTRT1? The parameter file RUN_NAME.ER1 was not found.

Action: The ER1 file was not found for the current simulation (RUN_NAME). Copy the file EXAMPLE.ER1 to RUN_NAME.ER1 and edit it as necessary. Execute the program again.

Code: 23
SORTS1? Fewer than 3 points sorted for any time.

Action: Only one or two simulation points were applicable for the sort times specified. There are three possible causes for this condition:

(1) if this message appears when the sort times are defaulted (CHECK5 is set to 0. in the ER3 file), the number of observers will probably have to be increased to give a good resolution of the downwind concentration field. (The number of observers is NOBS in the ER2 file with a maximum (MAXNOB) given in DEGADIS2.DEC.). As a rule of thumb, one gets good resolution of the downwind concentration field if the ratio: (secondary source duration / number of observers) is less than about 10 seconds (or 20 at most).

(2) The sort times specified in the ER3 file were before the simulation had developed significantly. This is only applicable when the user is specifying the sort times (i.e. when CHECK5 is set to 1. in the ER3 file). Increase the time of the first sort (ERT1), and rerun the program.

(3) The sort times specified in the ER3 file were after the gas was below the lowest concentration of interest. This is only applicable when the user is specifying the sort times (i.e. when CHECK5 is set to 1. in the ER3 file). Increase the time of the first sort (ERT1), and rerun the program. If additional results are desired for later times, restart the simulation and specify a lower concentration of interest in the input step (lower CCLOW in DEGADISIN).

Code: 24
TPROP? Trial and error loop compromised.

Action: TPROP estimates the temperature of a mixture based upon the composition and enthalpy of the mixture. Ensure the properties for the diffusing species are entered correctly and execute the simulation again.

Code: 25
TPROP? Isothermal density loop compromised.

Action: This error should never occur, but if it does, rebuild the model from the original files and run the simulation over.

Code: 26
TPROP? Invalid entry flag in ADIABAT.

Action: This is a programming diagnostic and should never occur. If it does, rebuild the model from the original files.

Code: 27
Reserved

Code: 28
TPROP? IGEN request too large in SETDEN.

Action: The subroutine SETDEN (in TPROP) performs a series of adiabatic mixing calculations with a specified gas mixture and ambient air and places the result in the array DEN(5,IGEN). This error indicates more points are needed in DEN than were originally requested. Increase the allocation for DEN by changing the value of IGEN in DEGADISIN.DEC and reinstalling DEGADIS.

Code: 29
PHIF? Flag IPHIFL is out of bounds.

Action: Proper values of IPHIFL are integers between 1 and 5 inclusive. Although values of IPHIFL are entered in the ER1 file as real numbers, they should be in this range. Check the ER1 file and execute the program again.

Code: 30
SSSUP/SDEADIS2? Concentration greater than RHOE.

Action: If the concentration of the contaminant becomes greater than the pure component density for an isothermal simulation, this error will occur. However, this situation should never occur. Check the input conditions and execute the program again.

Code: 31
SSSUP? Concentration greater than RHOE.

Action: If the concentration of the contaminant becomes greater than the pure component density for an isothermal simulation, this error will occur. However, this situation should never occur. Check the input conditions and execute the program again.

Code: 32
PSS? Sz convergence failure.

Action: This is a programming diagnostic and should never occur. If it does, check the input conditions and execute the program again.

Code: 33
SSG? Sz convergence failure.

Action: This is a programming diagnostic and should never occur. If it does, check the input conditions and execute the program again.

1. REPORT NO.	2.	3. RECIPIENT'S ACCESSION NO
4. TITLE AND SUBTITLE DEGADIS (DEnse GAs DISpersion) - Version 2.1		5. REPORT DATE June 1989 6. PERFORMING ORGANIZATION CODE
7. AUTHOR(S) T. O. Spicer and J. A. Havens		8. PERFORMING ORGANIZATION REPORT NO
9. PERFORMING ORGANIZATION NAME AND ADDRESS		10. PROGRAM ELEMENT NO. 11. CONTRACT/GRANT NO. EPA Contract #68-02-4351
12. SPONSORING AGENCY NAME AND ADDRESS U.S. Environmental Protection Agency Office of Air Quality Planning and Standards Source Receptor Analysis Branch Research Triangle Park NC 27711		13. TYPE OF REPORT AND PERIOD COVERED 14. SPONSORING AGENCY CODE

15. SUPPLEMENTARY NOTES
EPA Project Officer: Dave Guinnup

16. ABSTRACT

An improved Jet-Plume model has been interfaced with DEGADIS to provide for prediction of the trajectory and dilution of elevated dense gas jets to ground contact. DEGADIS predicts the ensuing ground-level plume dispersion. The Jet-Plume model provides for:
--automatic adjustment of integration step-size (using the Runge-Kutta-Gill method as in DEGADIS);
--elliptical plume shape (cross-section), with air entrainment specified consistent with the Pasquill-Gifford plume dispersion coefficient representation of atmospheric turbulent entrainment;
--user specification of averaging time;
--ground reflection when the plume (lower) boundary reaches ground level; and
--application to scenarios where the plume remains aloft.
